Preface

Reported Tuberculosis in the United States, 2014 presents summary data for tuberculosis (TB) cases verified and counted in 2014. Report of Verified Case of Tuberculosis (RVCT) forms are submitted to the Division of Tuberculosis Elimination (DTBE), Centers for Disease Control and Prevention (CDC), by 60 reporting areas (the 50 states, the District of Columbia, New York City, Puerto Rico, and seven other jurisdictions in the Pacific and Caribbean). First released in 1993, the RVCT was expanded in 2009 to collect additional information for each reported TB case in order to better monitor trends in TB and TB control.

Reported Tuberculosis in the United States, 2014 is similar to previous publications (see page xi, #19) and contains an Executive Commentary, Technical Notes, seven major data sections, and appendices. The Executive Commentary includes highlights of the 2014 data, and the Technical Notes section provides information about how the data were collected and reported; these sections are included to help the reader interpret the data.

Morbidity Trend Tables present trends in the overall TB case counts and case rates for the United States and the United States Affiliated Pacific Islands by selected demographic, clinical, and genotypic characteristics. *Morbidity Tables, 2014* present overall case counts and case rates for the United States and other jurisdictions by selected demographic and genotypic characteristics for the most recent year for which data are available. *Morbidity Tables, 2012* present overall case counts for the United States by selected demographic and clinical characteristics for the most recent year for which data are available on certain follow-up variables that require a longer data collection period. *Morbidity Tables, Reporting Areas, 2014* present TB case counts and case rates by state and by other jurisdictions with tables of selected demographic and clinical characteristics. *Morbidity Tables, Reporting Areas, 2012*

present data for the most recent year for which data are available on certain follow-up variables that require a longer data collection period. *Morbidity Tables, Metropolitan Statistical Areas, 2014* provide TB case counts and case rates by metropolitan statistical areas (MSAs: see *Technical Notes*, page 9, for further details) with tables of selected demographic and clinical characteristics. *Surveillance Slide Set, 2014* presents figures from the annual surveillance slide set, which emphasize key recent trends in TB epidemiology in the United States. The slides with accompanying text can also be viewed and downloaded from the DTBE website accessible at <http://www.cdc.gov/tb/>.

The current *Tuberculosis Case Definition for Public Health Surveillance and Recommendations for Reporting and Counting Tuberculosis Cases* are provided in Appendices A and B, respectively (pages 171 and 172). *National Surveillance for Severe Adverse Events Associated with Treatment for Latent Tuberculosis Infection - Reporting Information* is provided in Appendix C (page 181). *Genotyping Background Information and Glossary* is provided in Appendix D (page 182).

Executive Commentary

Executive Commentary

Highlights of 2014 Report

Since 1953, in cooperation with state and local health departments, the United States national tuberculosis program has collected information on each newly reported case of tuberculosis (TB) disease in the United States. Each individual TB case report (Report of Verified Case of Tuberculosis or RVCT) is submitted electronically. Following are the highlights of the 2014 report.

1. Updated case counts for each year from 1993 through 2013, in addition to new 2014 data.
2. Case count for 2014: 9,421 TB cases were reported to CDC from the 50 states and the District of Columbia (DC), representing a 1.5% decrease from 2013 (Table 1).
 - Twenty-one states reported increased case counts from 2013 (Table 30).
 - California, Texas, New York, and Florida accounted for 51% of the national case total (Table 31).
 - Asians exceeded all other racial or ethnic groups with the largest percentage of total cases (32%, Table 2). Almost all Asians with TB were in persons born outside the United States (95.5%, Table 3).
 - Hispanics comprised the second largest racial or ethnic group (29%, Table 2). Many Hispanics with TB were born in the United States (24.0%, Table 3)
 - Blacks or African Americans born in the United States represented 37% of TB cases in U.S.-born persons (Table 18) and accounted for 13% of the national case total.
 - Asians born outside the United States represented 46% of TB cases in foreign-born persons (Table 19) and accounted for 30% of the national case total.
3. Case rates: In 2014, the TB case rate declined from 3.02 to 2.96 per 100,000 persons, representing a 2.2% decrease from 2013 (Table 1).
 - Ten states and DC reported rates above the national average (Table 30).
 - The TB case rate was 1.2 per 100,000 for U.S.-born persons and 15.4 for foreign-born persons (Table 5).
 - Asians continued to have the highest case rate (17.8 per 100,000 persons) among all racial or ethnic groups (Table 2).
4. Burden among the foreign-born: In 2014, the percentage of cases occurring in foreign-born persons increased to 66% of the national case total (Table 5). This percentage has risen steadily since 1993.
 - In 35 states, and the District of Columbia, $\geq 50\%$ of TB cases occurred among foreign-born persons (Table 34).
 - The top five countries of origin of foreign-born persons with TB were Mexico, the Philippines, India, Vietnam, and China (Table 6).
5. Drug resistance: 1.0% of reported cases in 2014 had primary multidrug resistance, which is defined as no previous history of TB disease and resistance to at least isoniazid and rifampin (Table 9). This percentage has remained stable, fluctuating between 0.9% and 1.3% since 1996.
6. HIV status: In 2014, 6% of persons with TB were HIV positive.
 - The percentage of persons with TB who were HIV positive has dropped steadily since HIV test results were first reported in 1993 (Table 11).
7. Genotype surveillance coverage: In 2014, genotype surveillance coverage was 95.3%.
 - Genotype surveillance coverage has increased steadily since 2004. Thirty-nine states met or exceeded the national target of 94% genotype surveillance coverage in 2014 (Table 53). Among genotyped cases during 2012–2014, 21.6% were clustered, suggesting recent transmission (Table 23).

Tuberculosis in the United States

In 2014, the reported number of TB cases (9,421) and case rate (3.0 cases per 100,000) both decreased; these represented declines of 1.5% and 2.2%, respectively, compared to 2013. Since the 1992 TB resurgence peak in the United States, the number of TB cases reported annually has decreased by 65% (Table 1).

TB case rates vary by factors such as age, race and ethnicity, and country of origin. The proportion of total cases occurring in foreign-born persons has been increasing steadily since 1993. In 2014, 66% of TB cases occurred in foreign-born persons, an all-time high. Foreign-born persons have accounted for the majority of TB cases in the United States every year since 2001. Moreover, the case rate among foreign-born persons in 2014 was approximately 13 times higher than among U.S.-born persons (Table 5).

Tuberculosis deaths (compiled by the National Center for Health Statistics) increased by 8.8%, from 510 deaths in 2012 to 555 deaths in 2013. The number of TB deaths reported annually has decreased by 67% since 1992 (Table 1).

Age

Since 1993, TB case rates have declined annually for almost all age groups. In 2014, TB case rates continued the trend with declines in all age groups except children < 15 years of age and young adults 15-24 years old, which remained the same as the previous year at 0.8/100,000 and 2.2/100,000, respectively. The highest burden of disease continues to be among older adults. In 2014, adults ≥ 65 years old had a case rate of 4.8 cases per 100,000, while children ≤ 14 years old had the lowest rate at 0.8 cases per 100,000 (Table 4).

Race and Ethnicity

In 2003, the race and ethnicity category “non-Hispanic, Asian or Pacific Islander” was split into “non-Hispanic Asian” and “non-Hispanic Native Hawaiian or Other Pacific Islander.” In 2014, Asians had the highest TB case rate at 17.8 cases per 100,000, which was a slight decrease from 18.5 in 2013. Native Hawaiians or Other Pacific Islanders had the second-highest TB case rate at 16.9 cases per 100,000, which is an increase compared to 11.4 cases per 100,000 reported in 2013. Owing to low case numbers among Native Hawaiians or other Pacific Islanders, case rates fluctuate and changes must be interpreted with caution (Table 2).

Since 1993, TB case rates have declined in almost all racial and ethnic groups: among Hispanic or Latinos, the decline has been from 19.9 to 5.0 cases per 100,000 (-75%); among non-Hispanic blacks or African

Americans, from 28.5 to 5.1 cases per 100,000 (-82%); among American Indian or Alaska Natives, from 14.0 to 5.4 cases per 100,000 (-61%); among non-Hispanic whites, from 3.6 to 0.7 cases per 100,000 (-81%); and among Asians, from 41.2 to 18.7 cases per 100,000 (-55%). In 2014, the TB case rate for Asians remained over three times higher than that for Hispanics or blacks or African Americans (Table 2).

Origin of Birth

Since 1993, the TB case rate among U.S.-born persons has declined annually. In 2014, the TB case rate for U.S.-born persons was 1.2 cases per 100,000, representing an 84% decrease from 7.4 cases per 100,000 in 1993. The TB case rate among foreign-born persons also declined during the same interval, though the decline was less substantial. In 2014, the TB case rate among foreign-born persons was 15.4 cases per 100,000, representing a 55% decrease from 34.0 cases per 100,000 in 1993 (Table 5).

The proportion of TB cases among persons born in the United States has also declined annually since 1993. In 2014, 34% of TB cases were among U.S.-born persons compared to 69% in 1993 (Table 5). In 36 states, and the District of Columbia, ≥ 50% of TB cases occurred among foreign-born persons. In 8 states (Colorado, Maine, Maryland, Massachusetts, Nebraska, New Jersey, New York, Utah, Virginia, Washington, Wisconsin), ≥ 80% of TB cases occurred among foreign-born persons (Table 34).

Country of Origin and World Region

From 2010 through 2014, the top five countries of origin of foreign-born persons with TB were Mexico, the Philippines, India, Vietnam, and China (Table 6). The distribution of TB cases by world region of origin reflects immigration patterns among persons settling in the United States. Of the 6,215 TB cases reported among foreign-born persons in 2014, 37% occurred among persons born in the Americas region, and 32% occurred among persons born in the Western Pacific region (Table 20). From 1993 through 2014, the proportion of cases increased among persons born in the Eastern Mediterranean region (3% in 1993 to 5% in 2014), the Southeast Asia region (6% in 1993 to 14% in 2014), and the Africa region (2% in 1993 to 8% in 2014) (Table 20).

Multidrug-resistant Tuberculosis

The proportion of patients with primary multidrug-resistant (MDR) TB, which is defined as no previous history of TB disease and resistance to at least isoniazid and rifampin, decreased from 3% in 1993 to 1.3% in 1996. From 1996 to 2014, the percentage of primary

MDR TB cases has fluctuated between 1.3 and 0.9%. Since 1996, the percentage of U.S.-born patients with primary MDR TB has remained below 1%. However, of the total number of reported primary MDR TB cases, the proportion occurring in foreign-born persons increased from 25% (103 of 407) in 1993 to 85% (57 of 67) in 2014 (Table 9).

Extensively Drug-resistant Tuberculosis

CDC has included an updated case count of extensively drug-resistant (XDR) TB cases from 1993 to 2014 in the slide set that accompanies this report. XDR TB is defined as resistance to isoniazid and rifampin, plus resistance to any fluoroquinolone and at least one of three injectable second-line anti-TB drugs (i.e., amikacin, kanamycin, or capreomycin). Two cases were reported as XDR TB in 2014, compared to five cases in 2013, two cases in 2012, five cases in 2011, one case in 2010, and 0 cases in 2009. Of the 15 XDR TB cases reported since 2009, 11 were among foreign-born persons.

Tuberculosis Therapy

The proportion of TB patients prescribed an initial treatment regimen including isoniazid, rifampin, pyrazinamide, and ethambutol increased from 40.3% in 1993 to 85.4% in 2012. The proportion of patients who completed therapy within 1 year increased from 63.4% in 1993 to 89.4% in 2012 (the latest year for which complete outcome data are available). The proportion of persons receiving directly observed therapy for at least a portion of the treatment duration also increased from 36% in 1993 to 91% in 2012, the latest year for which complete outcome data are available (Table 10).

HIV Status

Between 2013 and 2014, the proportion of persons with TB who reported HIV test results has remained high at 89% for all ages and 95–93% for persons 25–44 years old (Table 11). The percentage of persons with TB who reported HIV test results and who were HIV-positive was 6% in 2014, representing a 7% decrease from 2011 (Table 11). Among persons 25–44 years of age, 9% of persons with TB who reported HIV test results were HIV-positive in 2014, decreasing from 11% in 2011 (Table 11). The percentages have declined since 1993, when 48% of persons with TB of all ages with HIV test results reported HIV-positive results; among persons between 25–44 years of age, the percentage was 63% in 1993 (Table 11). The American Thoracic Society and the Infectious Diseases Society of America recommend that all TB patients be counseled and tested for HIV.¹

¹ CDC. Treatment of tuberculosis. American Thoracic Society, CDC, and Infectious Diseases Society of America. MMWR 2003;52(No. RR-11).

Genotyping

TB genotyping is a laboratory-based analysis of the genetic material of the bacteria that cause TB disease. In the United States, routine genotyping of isolates from culture-positive TB cases started in 2004, and results are reported by CDC's National Tuberculosis Genotyping Service (NTGS). TB genotyping surveillance coverage, defined as the proportion of culture-positive TB cases with a genotype result, has increased from 52.6% in 2004 to 95.3% in 2014 (Table 13). TB genotype clusters are defined as two or more cases with matching genotypes in the same county during a 3-year time period. Cases that are clustered suggest recent transmission, while unique cases are more likely attributable to reactivation of infection that was acquired in the past. Among genotyped cases during 2012–2014, 21.6% were clustered (Table 23). During this period, the percentage of clustered cases among U.S.-born persons with TB was 35.5%, compared to 14.3% among foreign-born persons diagnosed with TB in the United States (Table 22). Among 4,544 cases in clusters during 2012–2014, 908 cases were in 93 high-alert clusters, 1,036 cases were in 338 medium-alert clusters, and 2,600 cases were in 1,063 non-alerted clusters (Table 22; see Appendix D for cluster definitions). Among all cases genotyped in 2014, 1.6% had TB caused by *Mycobacterium bovis*, and the majority of these *M. bovis* cases (77.6%) were foreign-born (Table 15). Technical notes describe changes made in the *M. bovis* case definition, which resulted in a 13.9% reduction in the average of annual *M. bovis* case counts (n=105) compared to average annual counts that would have been reported without these changes (n=122).

United States Affiliated Pacific Islands (USAPI)

The USAPI consist of six jurisdictions in the Pacific Ocean: American Samoa, the Commonwealth of the Northern Mariana Islands, Guam, Federated States of Micronesia, Republic of the Marshall Islands, and Republic of Palau. As a result of their affiliations with the United States, the USAPI receive U.S. federal government funding, including CDC cooperative agreement funding for domestic TB control program activities. In 2014, the USAPI had 410 reported cases of TB. Among these, 204 (50%) were male, 79 (19%) were aged less than 15 years and 123 (30%) were aged 25–44 years. In addition, 46 (11%) were not born in the USAPI jurisdictions or the United States, and of those, 41 (89%) emigrated from the Republic of the Philippines. Some other data highlights of the 410 reported USAPI cases are that 334 (81%) were diagnosed with pulmonary disease only, 185 (45%) had a positive culture for *Mycobacterium tuberculosis*; < 1% had MDR TB, and 127 (31%) were unemployed. Genotype surveillance coverage for USAPI was 92.4% in 2014.

Puerto Rico

In 2014, the Commonwealth of Puerto Rico reported 44 TB cases to CDC, a case rate of 1.2 per 100,000 persons. Among those cases, 33 (75%) were male, two (5%) were < 25 years old, and 35 (80%) were > 45 years old. Of the 44 reported cases, 7 were born outside of Puerto Rico, and of those, 5 (71%) emigrated from the Dominican Republic. The majority of reported cases (86%) were diagnosed with pulmonary disease only, 91% had positive cultures for *Mycobacterium tuberculosis*, none had MDR TB, and 39% were unemployed. Genotype surveillance coverage for Puerto Rico was 95.0% in 2014.

Summary

Both the absolute number of TB cases and the TB case rate in the United States have declined each year since 1993. The total case count of 9,421 and case rate of 3.0 per 100,000 persons represent steady progress toward the goal of TB elimination in the United States (< 1 case per 1,000,000 population). However, despite consistent declines in TB cases and case rates over the past 60 years, this year's decline in the rate of TB (-2.2%) was the smallest decrease in more than a decade. This minimal decline stresses the importance of refining our strategies in surveillance, contact investigations, and screening and treating contacts with latent TB infection. Focusing on populations at highest risk for TB and latent TB infection, such as persons born in high-burden countries, is also key.

Foreign-born persons continue to be disproportionately affected by TB; in 2014, the proportion of persons with TB who were foreign-born continued to increase to 66% of total cases. Global TB disease burden and the incidence in the United States are closely related, highlighting the need to strengthen existing support for TB control efforts abroad. This is particularly true as relates to the countries of origin of immigrants that contributed over half of the U.S. foreign-born TB patients in 2014: Mexico, the Philippines, India, Vietnam and China (Table 6). These top countries of birth for foreign-born persons with TB are further explored in Table 35, which provides data by state. Table 20 further analyzes all countries of birth for cases among foreign-born persons, and arranges the data by region; the largest proportion is from the Americas, followed by the Western Pacific region. In Table 21, an analysis of risk factors leading to TB disease is provided by origin of birth and race/ethnicity. Table 36 stratifies TB in foreign-born persons by their immigration status at first entry into the United States and Table 37 provides information on the number of years a foreign-born TB patient has been in the

United States; both of these tables show data at the state level. In Table 65, data on TB cases among foreign-born persons are available for metropolitan statistical areas.

CDC and the Division of Tuberculosis Elimination are seeking to strengthen surveillance capacity and support collaborations to address TB among persons who cross borders. Efforts are underway to enhance surveillance and measure burden of binational TB cases along the U.S.-Mexico border, an important region for focusing TB control efforts, as 20% of foreign-born TB cases were born in Mexico. To achieve TB elimination, intensified efforts are needed to address the persistent disparities that exist between U.S.-born and foreign-born persons. Ongoing surveillance and improved TB control and prevention activities, including a sustained focus on domestic TB control, a strengthened effort to diagnose and treat latent TB infection, and continued support of global TB control initiatives are especially necessary in light of the small decline of TB case rates in 2014.

Technical Notes

Technical Notes

National Tuberculosis Surveillance System

Reporting areas (i.e., the 50 states, the District of Columbia, New York City, Puerto Rico, and other U.S. jurisdictions in the Pacific and Caribbean¹) report tuberculosis (TB) cases to CDC's National TB Surveillance System (NTSS) using a standard case report form, Report of Verified Case of Tuberculosis (RVCT). TB cases are verified according to the Tuberculosis Case Definition for Public Health Surveillance in Appendix A. TB cases are reported and counted according to the Recommendations for Reporting and Counting Tuberculosis Cases in Appendix B.

TB Case Definition

In 2009, the case definition was modified. TB cases are verified according to the following specified laboratory and clinical criteria (see Appendix A, page 171).

Laboratory criteria for diagnosis

A case may be verified by the laboratory case definition with at least one of the following criteria: 1) isolation of *M. tuberculosis* complex from a clinical specimen, OR 2) demonstration of *M. tuberculosis* complex from a clinical specimen by nucleic acid amplification test (NAAT), OR 3) demonstration of acid-fast bacilli (AFB) in a clinical specimen when a culture has not been or cannot be obtained or is falsely negative or contaminated.

Clinical case criteria

A case may be verified by the clinical case definition in the presence of ALL of the following clinical criteria: 1) a positive tuberculin skin test (TST) result or positive interferon gamma release assay (IGRA) result for *M. tuberculosis*, AND 2) other signs and symptoms compatible with TB (e.g., abnormal chest radiograph, abnormal chest computerized tomography scan or other chest imaging study, or clinical evidence of current disease, AND 3) treatment with two or more anti-TB drugs, AND 4) a completed diagnostic evaluation.

Provider Diagnosis

Provider diagnosis is not a component of the case definition for TB as described in Appendix A. However, when cases of TB are diagnosed but do not meet either the clinical or laboratory case definition, reporting areas have the option of verifying TB cases based on provider diagnosis as described in Appendix B. Through 2008,

¹Other U.S. jurisdictions include American Samoa, the Commonwealth of the Northern Mariana Islands, the Federated States of Micronesia, Guam, the Republic of the Marshall Islands, the Republic of Palau, and U.S. Virgin Islands

the RVCT did not collect information on IGRA results. If an IGRA was performed in lieu of the TST, then the RVCT would have indicated that the TST was not performed. Thus, culture- and smear-negative cases without a TST that are diagnosed by a positive IGRA result prior to 2008 were considered to have been confirmed by provider diagnosis. However, starting in 2009, positive results for an IGRA are included as part of the clinical case definition for TB confirmation. Anergic patients with a clinical presentation consistent with TB but without laboratory evidence of *M. tuberculosis* complex would also be an example of provider diagnosis and one which has not changed over time.

TB Case Verification Criteria Calculation

The software for TB surveillance developed by CDC includes a calculated variable for TB case verification called "Vercrit," which was modified in 2009. The new variables, Nucleic Acid Amplification Test Result, Interferon Gamma Release Assay (IGRA) for *Mycobacterium tuberculosis* at Diagnosis, and Initial Chest CT Scan or Other Chest Imaging Study were added in the Vercrit calculation.

"Vercrit" is calculated by using the following criteria in hierarchical order:

1. Positive culture
2. Positive nucleic acid amplification test
3. Positive acid-fast bacilli test
4. Clinical case confirmation
5. Provider diagnosis

Changes in Reporting and Counting TB Cases

In 2009, the Recommendations for Reporting and Counting Tuberculosis Cases in Appendix B were modified. TB cases that are verified but not countable for morbidity statistics are now reported to CDC as a measure of programmatic and case management burden. However, data on noncountable TB cases are incomplete and not included in this report.

The recommendations for counting TB cases among immigrants, refugees, and foreign visitors were revised based on the recommendations in the 2007 Technical Instructions for Tuberculosis Screening and Treatment for Panel Physicians.² Regardless of Panel Physician classification or citizenship status, immigrants and refugees examined after arriving in the United States and diagnosed with clinically active TB requiring anti-TB

²CDC. *Immigration Requirements: Technical Instructions for Tuberculosis Screening and Treatment, 2007*. Atlanta: CDC, Division of Global Migration and Quarantine, revised September 2007; http://www.cdc.gov/ncidod/dq/pdf/ti_tb_8_9_2007.pdf.

medications should be reported and counted by the locality of their current residence at the time of diagnosis. Foreign visitors diagnosed with TB, receiving anti-TB therapy, and planning to remain in the United States for 90 days or more should be reported and counted by the locality of current residence.

New and Expanded RVCT Variables

Data on demographic, clinical, laboratory, initial treatment, and treatment outcomes are collected through the RVCT's three data collection reports:

1. Report of Verified Case of Tuberculosis: for all patients with a verified case of TB.
2. Initial Drug Susceptibility Report (Follow-Up Report 1): for all patients who had a culture that was positive for *M. tuberculosis* complex.
3. Case Completion Report (Follow-Up Report 2): for all patients who were alive when TB was diagnosed.

In 2009, the RVCT was modified and expanded to include 11 additional variables. Modifications to the RVCT accommodate the changing epidemiology of TB in terms of risk factors, new drug treatments, and enhanced laboratory capacity for diagnostic tests. The 2014 Report contains many tables reflecting the addition of these variables.

The instructions for completing the RVCT forms and the definitions for all data items are available at: CDC. Report of Verified Case of Tuberculosis (RVCT) Instruction Manual. Atlanta, GA: U.S. Department of Health and Human Services, CDC, 2009. <http://www.cdc.gov/tb/programs/rvct/InstructionManual.pdf>.

Tabulation and Presentation of TB Data

This report presents summary data for TB cases reported to CDC in 2014. TB cases are tabulated by year in which the reporting area verified that the patient had TB and included the patient in its official annual TB case count. Since 2004, the published report has reflected updated information on the numbers of cases of confirmed TB for each year from 1993 onward. Totals for the United States include data from the 50 states, the District of Columbia (DC), and New York City.

Trend data are presented in Tables 1 through 15. Age group tabulations are based on the patient's age in the month and year the patient was reported to the health department as a suspected TB case. State or metropolitan area data tabulations are based on the patient's residence at diagnosis of TB.

Rates

Rates are expressed as the number of cases reported each calendar year per 100,000 persons. Population denominators used in calculating TB rates were based on official census and midyear postcensal estimates from the U.S. Census Bureau. In Tables 1, 30, and 31, the U.S. total populations for 2000–2010 were taken from the U.S. Census Annual Estimates of the Resident Population for the United States, Regions, States, and Puerto Rico (April 1, 2000 to July 1, 2010); populations for 2011–2014 were taken from the U.S. Census Annual Estimates of the Resident Population for the United States, Regions, States, and Puerto Rico (April 1, 2010 to July 1, 2014).

In 2003, two modifications were made to the RVCT form: 1) entries for multiple race (two or more races reported for a person) were allowed, and 2) the previous category of "Asian/Pacific Islander" was divided into "Asian" and "Native Hawaiian or Other Pacific Islander." To calculate rates in Table 2, denominators for 2000–2014 were obtained from the National Population Estimates for the 2000s: Monthly Postcensal Resident Population, by single year of age, sex, race, and Hispanic origin and National Population Estimates for the 2010s: Monthly Postcensal Resident Population, by single year of age, sex, race, and Hispanic origin. The population source for nativity is the Current Population Survey and is used to calculate case rates for U.S. and foreign-born TB. This population source includes populations for the 50 states and D.C., those born abroad of U.S. parents, and those born in U.S. outlying areas (the U.S.-affiliated areas) as the U.S-born population.

To calculate rates for Table 4, denominators were obtained from the Annual Estimates of the Resident Population by Sex and Five-Year Age Groups for the United States (April 1, 2000 to July 1, 2009) and Annual Estimates of the Resident Population for Selected Age Groups by Sex for the United States, States, Counties, and Puerto Rico Commonwealth and Municipios (April 1, 2010 to July 1, 2014). In Table 5, the populations for U.S.-born and foreign-born persons for 1993 and 1994 were obtained from Quarterly Estimates of the United States Foreign-born and Native Resident Populations: April 1, 1990–July 1, 1999. Denominators for computing the 1995–2014 rates were based on extrapolations from the U.S. Census Current Population Survey (July Supplement).

Denominators for computing 2014 rates in Table 17 were obtained from U.S. Census Monthly Postcensal Resident Population, by single year of age, sex, race,

and Hispanic origin. In 2004, the method for calculating the annual percentage change in the TB case rate was modified. Unrounded figures are applied to calculate the percentage change in the case rate.

Mortality Data

The annual mortality rate is calculated as the number of deaths due to TB in that year, divided by the estimated population for the year, multiplied by 100,000 (Table 1). The number of deaths for 2013 was obtained from the Centers for Disease Control and Prevention, National Center for Health Statistics. Multiple Cause of Death 1999-2013 on CDC WONDER Online Database, released 2015. Data are from the Multiple Cause of Death Files, 1999-2013, as compiled from data provided by the 57 vital statistics jurisdictions through the Vital Statistics Cooperative Program. Finalized numbers of deaths for 2014 were not available at the time of this publication.

Drug Resistance

Drug-resistance patterns are displayed in separate tables with drug-resistance trend data by previous TB status and origin of birth. Isoniazid (INH) resistance and multidrug resistance (MDR) are shown in Tables 8 and 9, respectively.

Completion of Tuberculosis Therapy

Tables 10, 59, 60, and 61 present rates of completion of TB therapy (COT). Data collected by RVCT Follow Up Report-2 on date and reason therapy stopped (e.g., patient completed therapy) were used to calculate rates of COT. Cases were stratified by the indicated length of therapy, based on American Thoracic Society/CDC/Infectious Diseases Society of America treatment guidelines³ in effect during the period covered, and the patient's initial drug-susceptibility test results, age, and site of disease.

In Table 60, the first column shows the total number of cases reported during 2012. The remaining columns are grouped under three headings: therapy of 1 year or less indicated, therapy greater than 1 year indicated, and overall. Patients eligible to complete therapy within 1 year had to have been alive at diagnosis, and initiated therapy with at least one drug. Eligible patients did not have rifampin resistance, did not die within 1 year of initiating therapy, did not move out of country within 1 year of initiating therapy, and did not have meningeal TB, bone and joint TB or TB of the central nervous system, regardless of age. In addition, TB patients un-

der the age of 15 were not eligible to complete therapy within 1 year if they had disseminated disease (defined as miliary tuberculosis and/or a positive tuberculosis blood culture). Patients with culture-negative disease, those with an unknown culture status, and those with culture-positive disease but unknown initial drug-susceptibility test results were included under the category of 1 year or less of therapy indicated. Each group under an indicated length of therapy has an initial column showing the number of cases in persons who were alive at diagnosis and prescribed an initial regimen of one or more drugs, and who did not die during therapy. This number was used as the denominator in COT rate calculations.

COT rates, shown as percentages, were only calculated for areas reporting reason therapy stopped for at least 90% of cases shown in the overall column. For the group with an indicated length of therapy of 1 year or less, rates are shown for both COT in 1 year or less ($\text{COT} \leq 1$ year) and for COT, regardless of duration (i.e., duration of therapy ≤ 1 year, >1 year, or unknown). For $\text{COT} \leq 1$ year, the numerator included only those patients completing therapy in ≤ 366 days (based on the dates therapy started and stopped). Patients with missing dates were classified as "treatment not completed" for this calculation.

Rates of COT, regardless of duration, were calculated by dividing the number of patients reported as having completed therapy by the number of total eligible patients. Patients with an outcome other than completed therapy (i.e., moved, lost, refused treatment, or other) were classified as "treatment not completed." Patients with an unknown outcome were also classified as "treatment not completed." For the remaining two groups of indicated therapy length (greater than 1 year and overall), only rates of COT, regardless of duration, are presented. Table 10 provides rates for $\text{COT} \leq 1$ year and for COT, regardless of duration, only for the group with an indicated therapy of 1 year or less. Table 59 presents rates of COT by ethnicity and non-Hispanic race and by state for those in whom therapy less than 1 year was indicated.

Because streptomycin is no longer being used as part of the standard treatment for TB disease, streptomycin has been removed from the calculated variable for initial drug regimen. Consequently, a separate column for the treatment regimen of isoniazid, rifampin, pyrazinamide (IRZ), ethambutol, streptomycin (E/S) is no longer reported in Tables 10 and 49.

³CDC. Treatment of Tuberculosis, American Thoracic Society, CDC, and the Infectious Diseases Society of America. MMWR 2003;52(No.RR-11):1-77.

Site of TB Disease

Miliary disease is classified as both an extrapulmonary and a pulmonary form of TB (Tables 7, 38, and 39). In publications prior to 1997, miliary disease was classified as extrapulmonary TB unless pulmonary disease was reported as the major site of TB disease. Beginning in 2009, miliary disease could not be classified as a site of TB disease because it is a clinical or radiologic finding and should be recorded under **Initial Chest Radiograph, Initial Chest CT Scan, or Other Chest Imaging Study**.

Reporting of HIV Status

Information on HIV status for persons with TB is shown in Tables 11 and 51 among those persons not dead at diagnosis; Table 11 additionally shows trend data for persons aged 25–44 years. The completeness of reporting on HIV status among persons with TB has significantly improved to 93% of TB cases tested among persons aged 25–44 years in 2014; however, this variable is still underreported among jurisdictions. Data on the HIV-infection status of persons with reported TB cases should be interpreted with caution. These data are not representative of all TB patients with HIV infection.

HIV testing is performed after a patient receives counseling and gives informed consent. TB patients who are tested anonymously may choose not to share the results of HIV testing with their health care provider. TB patients managed in the private sector may receive confidential HIV testing, but results may not be reported to the TB program in the health department. In addition, many factors may influence HIV testing of TB patients, including the extent to which testing is targeted or routinely offered to specific groups (e.g., 25- to 44-year-old males, injecting drug users, homeless persons), and the availability of and access to HIV testing services. These data may overrepresent or underrepresent the proportion of TB patients known to be HIV infected in a reporting area.

Primary Occupation for the Past Year

Table 48 reflects the modified 2009 RVCT variable, **Primary Occupation Within the Past Year**, which replaces the **Occupation Within Past 24 months of TB Diagnosis** in previous reports. Following the 2009 RVCT revision, “Multiple Occupation” was removed and the “Retired” and “Not Seeking Employment” categories were added.

Reason Therapy Stopped

Tables 12 and 57 now include a patient’s adverse reaction to anti-TB drug therapy as an option for the reason therapy stopped. The 2009 RVCT revision removed

the option of “Moved” as a valid response to the variable **Reason Therapy Stopped** and this option is not reported after 2009. Those cases entered as “Moved” as reason therapy stopped after 2009 are now included in the “Unknown” category.

Metropolitan Statistical Areas

Tables 62 through 66 present data by metropolitan statistical areas (MSAs) with an estimated 2014 population of 500,000 or more. MSAs are defined by the federal Office of Management and Budget, and the definitions were based on the application of the 2010 OMB standards to 2010 Census and 2006–2010 American Community Survey data announced as of February 2013 (<http://www.whitehouse.gov/sites/default/files/omb/bulletins/b-13-01.pdf>).

The MSA definitions apply to all areas except the six New England states; for these states, the New England County Metropolitan Areas (NECMAs) are used. MSAs are named for a central city in the MSA or NECMA, may include several cities and counties, and may cross state boundaries. For example, the TB cases and case rates presented for the District of Columbia in Table 30 include only persons residing within the geographic boundaries of the District. However, the TB cases and case rates for the Washington, D.C., MSA (Table 62) include persons residing within the several counties in the metropolitan area, including counties in Maryland, Virginia, and West Virginia.

A city/MSA with incomplete or unavailable data was not included in the tables and some cities’ or MSAs’ total numbers may be underreported owing to missing information.

National Tuberculosis Genotyping Service (NTGS)

NTGS laboratories primarily use two genotyping methods: spoligotyping and MIRU–VNTR. Both methods require only a small amount of culture material, provide digital results, and are relatively quick. IS6110-restriction fragment length polymorphism (IS6110-RFLP) and retrospective 24-locus MIRU-VNTR for older isolates can be performed, if requested, and may help in further differentiating genotype clusters. All isolates are prepared for long-term storage at genotyping laboratories or CDC.

Tuberculosis Genotyping Information Management System (TB GIMS)

In March 2010, TB GIMS was launched by CDC as a secure Web-based system to support ongoing use of TB genotyping data in TB control activities. TB GIMS facilitates systematic data collection of TB genotyping

results and integrates genotyping results with epidemiologic data collected by the National TB Surveillance System (NTSS) to form a national and centralized database. Primary users of TB GIMS include TB laboratories that submit isolates for genotyping, national CDC-contracted genotyping laboratories, state and local TB control programs, and CDC that apply this information for TB control activities.

Genotyping results from the national genotyping laboratories or CDC are uploaded into TB GIMS as they become available. Line-listed data from the National TB Surveillance System are also uploaded into TB GIMS weekly. Once genotyping results have been linked to individual patient surveillance data in TB GIMS, the record is considered complete. Complete records are essential for most of the applications of TB genotyping, including all reports and maps as well as using the outbreak detection system to identify potential chains of transmission and outbreaks.

There have been 18 system updates in adding new reports, data management functions, and other tools since TB GIMS was released in March 2010. As of June 2015, there were 522 local, state, and federal users of the system.

Genotype Clustering

A genotype cluster consists of two or more cases in a jurisdiction during a specified time period with *M. tuberculosis* isolates that share matching genotypes. The jurisdiction and time period used vary based on the specific application. Cases that are part of the same genotype cluster are likely to be related by TB transmission in some way; however, the cases may not be directly related (i.e., one case did not necessarily give TB to another case in the cluster) or recently related (i.e., both cases may have gotten TB from the same person, but the exposure may have happened years ago). While genotype clustering can be used to identify likely TB transmission, transmission must be confirmed using field data from contact investigations or other sources. In TB GIMS, clustering is defined as 2 or more cases with matching genotypes (spoligotype and 24-locus MIRU-VNTR) in a single county within a 3-year time period.

Mycobacterium bovis

For culture-confirmed TB cases that have been genotyped, *Mycobacterium bovis* can be defined primarily on the basis of spoligotyping results. The genotype-based definition for *M. bovis* required either (1) the absence of spoligotyping spacers 3, 9, 16, and 39–43; the presence of at least 1 of the spacers 29–32; and the presence of at least 1 of the spacers 33–36; or (2) the

absence of spacers 3, 9, 16, and 39–43 and ≥2 copies of the repeated sequence at MIRU locus 24, or (3) determination based on microbiologic expertise. Data reported for 2004–2014 exclude 107 cases of Bacillus Calmette-Guérin (BCG) *M. bovis*, which were defined as spoligotype 676773777777600 with x, y or z in the second MIRU position. These specifications represent changes in definitions from annual reports published prior to 2014, which included a spoligotyping-based definition that defined *M. bovis* predominantly by motifs ending in “600” and the prior inclusion of cases of BCG *M. bovis*. These changes result in a 13.9% reduction in the average of annual *M. bovis* case counts (n=105) compared to average annual counts that would have been reported without these changes (n=122).

Morbidity Trend Tables

Table 1. Tuberculosis Cases, Case Rates per 100,000 Population, Deaths, and Death Rates per 100,000 Population, and Percent Change: United States, 1953–2014

Year	Tuberculosis Cases					Tuberculosis Deaths			
	Number	Rate	Percent Change		Number ¹	Rate ¹	Percent Change		
			Number	Rate			Number	Rate	
1953	84,304	52.6	--	--	19,707	12.4	--	--	
1954	79,775	48.9	-5.4	-7.0	16,527	10.2	-16.1	-17.7	
1955	77,368	46.6	-3.0	-4.7	15,016	9.1	-9.1	-10.8

¹Official tuberculosis mortality statistics were compiled by the National Center for Health Statistics, CDC, and accessed at <http://wonder.cdc.gov/mcd-icd10.html> on Jul 2, 2015.

²Case data after 1974 are not comparable to prior years due to changes in the surveillance case definition that became effective in 1975.

³The large decrease in death rate in 1979 occurred because late effects of tuberculosis (e.g., bronchiectasis or fibrosis) and pleurisy with effusion (without mention of cause) are no longer included in tuberculosis deaths.

Percent change in tuberculosis death rates is calculated with rounded figures. See Technical Notes.

Note: 1993 to 2014 tuberculosis case counts and rates updated as of June 30, 2015, using the following sources: Bridged-Race 1990–1999 Intercensal Population Estimates for 1990–1999 (ftp://ftp.cdc.gov/pub/health_statistics/nchs/datasets/nvss/bridgepop/documentationbridgedintercena1.doc) (accessed July 15, 2015) and Intercensal Estimates of the Resident Population for the United States, Regions, States, and Puerto Rico: April 1, 2000 to July 1, 2010 (<http://www.census.gov/popest/data/intercensal/state/state2010.html>) (accessed July 15, 2015) and Annual Estimates of the Resident Population for the United States, Regions, States, and Puerto Rico: April 1, 2010 to July 1, 2014 (<http://www.census.gov/popest/data/national/totals/2014/index.html>) (accessed July 15, 2015).

Percentage change results reported to one decimal. Ellipses indicate data not available. See Surveillance Slides #2 and #3.

¹ Asian race category reporting includes Pacific Islander from 1993–2002.

² Native Hawaiian or Other Pacific Islander race first reported separately in 2003.

³ Indicates two or more races reported for a person. Category first reported in 2003. Does not include persons of Hispanic or Latino origin.

⁴ Persons of Hispanic or Latino ethnicity may be of any race or multiple race.

⁵ The higher count for unknown or missing race results for 1993 - 2001 reflect the impact of the transitional period of incorporating new race definitions for Asian, Native Hawaiian, and Multiple Race in 2003.

Note: Rates for 1993–1999 have been updated using Resident Population: Monthly Postcensal Resident Population, by single year of age, sex, race, and Hispanic origin (http://www.census.gov/popest/national/asrh/1990s/nat_monthly_resident.html) (accessed July 15, 2015). Denominators for computing 2000–2009 case rates were obtained from the National Population Estimates for the 2000s: Monthly Postcensal Resident Population, by single year of age, sex, race, and Hispanic origin (<http://www.census.gov/popest/data/national/asrh/2009/2009-nat-res.html>) (accessed July 15, 2015) Denominators for computing 2000–2014 case rates were obtained from the National Population Estimates for the 2010s: Monthly Postcensal Resident Population, by single year of age, sex, race, and Hispanic origin (<http://www.census.gov/popest/data/national/asrh/2014/files/NC-EST2014-ALLDATA-R-File10.csv>) accessed June 25, 2015).

Case counts for race categories (American Indian or Alaska Native, Asian, Black or African American, Native Hawaiian or Other Pacific Islander, and White) do not include persons of Hispanic ethnicity or multiple race.
Data for all years updated through June 5, 2015.
Ellipses indicate data not available.
See Technical Notes.
See Surveillance Slide #10.

Zero % (0) denotes <0.5%.

¹Includes unknown and missing.

Note: Previously published rates for 1993–1999 have been updated using Bridged-Race 1990–1999 Intercensal Population Estimates for 1990–1999 (http://ftp.cdc.gov/pub/health_statistics/nchs/datasets/nvss/bridgepop/documents/bridgeintercena1.doc) (accessed July 15, 2015). Denominators for computing 2000–2014 case rates were obtained from the Annual Estimates of the Resident Population by Sex and Five-Year Age Groups for the United States: April 1, 2000 to July 1, 2009 (http://www.census.gov/popest/data/historical/2000s/vintage_2009/index.html), and Annual Estimates of the Resident Population for Selected Age Groups by Sex for the United States, States, Counties, and Puerto Rico Commonwealth and Municipalios: April 1, 2010 to July 1, 2014 (<http://www.census.gov/popest/data/national/asrh/2014/index.html>) (accessed June 25, 2015).

Data for all years updated through June 5, 2015.

See Technical Notes.

Zero % (0) denotes <0.5%.

See Surveillance Slides #7 and #8.

Table 5. Tuberculosis Cases, Percentages, and Case Rates per 100,000 Population by Origin of Birth: United States, 1993–2014

Year	Total Cases	U.S.-born Persons			Foreign-born Persons ¹			Unknown or Missing (%)

2009	11,523	4,542	(39)	1.7	6,961	(60)	18.7	20 (0)
2010	11,161	4,374	(39)	1.6	6,778	(61)	17.7	9 (0)
2011	10,510	3,973	(38)	1.5	6,531	(62)	17.0	6 (0)
2012	9,941	3,655	(37)	1.4	6,278	(63)	15.9	8 (0)
2013	9,565	3,365	(35)	1.2	6,189	(65)	15.6	11 (0)
2014	9,421	3,188	(34)	1.2	6,215	(66)	15.4	18 (0)

¹Includes persons born outside the United States, American Samoa, the Federated States of Micronesia, Guam, the Republic of the Marshall Islands, Midway Island, the Commonwealth of the Northern Mariana Islands, Puerto Rico, the Republic of Palau, the U.S. Virgin Islands, and U.S. minor and outlying Pacific islands.

Note: Denominators for computing rates for years 1993–1994 were obtained from Quarterly Estimates of the United States Foreign-born and Native Resident Populations: April 1, 1990–July 1, 1999, located at <http://www.census.gov/poplulation/estimates/nation/nativity/fbtab001.txt> (accessed July 15, 2015). Denominators for computing the 1995–2014 rates are based on the U.S. Census Bureau, Current Population Survey (July Supplement) via Data Ferret (<http://dataferrett.census.gov/>).

Data for all years updated through June 5, 2015.
See Technical Notes.

Zero % (0) denotes <0.5%.
See Surveillance Slides #13, #14, #17, and #18.

¹Resistance to at least isoniazid. Isolates may be resistant to other drugs. Cases are culture positive with initial drug susceptibility testing done. Excludes cases with susceptibility testing not done or unknown for isoniazid. Cases have been susceptibility tested to at least isoniazid and rifampin.

²This column provides an overall total of all INH-resistant cases, including those where previous history of TB is unknown and origin or birth is unknown.

³Excludes cases where previous history of TB is unknown and cases where origin of birth is unknown.

⁴Includes persons born outside the United States, American Samoa, the Federated States of Micronesia, Guam, the Commonwealth of the Northern Mariana Islands, Midway Island, the Commonwealth of Puerto Rico, the Republic of Palau, the U.S. Virgin Islands, and U.S. minor and outlying Pacific Islands.

Note: Data for all years updated through June 5, 2015.

**Table 9. Tuberculosis Cases and Percentages, by Multidrug Resistance¹, Origin of Birth, and Previous History of TB:
United States, 1993–2014**

Year	All MDR ²	Total MDR ³						Multidrug Resistant TB Cases						Foreign-born ^{3,4} MDR

2002	(1.8)	(8.9)	(80.3)	(55.4)	(27.8)	(83.0)	(92.5)
2003	(1.4)	(8.1)	(81.3)	(56.5)	(28.5)	(83.6)	(92.8)
2004	(1.5)	(6.4)	(82.4)	(58.9)	(27.7)	(84.3)	(92.6)
2005	(1.3)	(5.5)	(83.7)	(57.9)	(29.6)	(84.0)	(92.5)
2006	(1.2)	(4.8)	(83.3)	(57.5)	(30.4)	(84.8)	(93.2)
2007	(1.1)	(4.6)	(83.8)	(56.3)	(32.9)	(85.6)	(93.9)
2008	(1.0)	(3.5)	(84.3)	(56.4)	(33.5)	(86.0)	(93.3)
2009	(0.9)	(3.0)	(84.7)	(59.7)	(30.3)	(88.8)	(95.6)
2010	(0.8)	(2.8)	(84.8)	(59.3)	(31.1)	(89.6)	(96.0)
2011 ⁵	(0.7)	(2.6)	(85.4)	(62.2)	(29.2)	(89.3)	(96.0)
2012 ⁵	(0.6)	(2.0)	(85.4)	(61.8)	(29.2)	(89.4)	(95.4)

¹ Includes persons alive at diagnosis.

² I=isoniazid; R=rifampin; Z=pyrazinamide; E=ethambutol. Excludes cases with no information on initial drug regimen; In 2014, 0.45% received no initial drug therapy, 0.17% were started on one drug, and 11.90% had an initial drug regimen other than IR, IRZ, or IRZE.

³ Includes persons alive at diagnosis with initial drug regimen of one or more drugs prescribed.

⁴ Therapy < 1 year indicated in persons alive at diagnosis with an initial regimen of one or more drugs prescribed, who did not die within one year of initiating therapy. Excludes persons with initial isolate rifampin resistant, or patient with bone and joint disease, meningeal disease or disease of the central nervous system, or pediatric patient (aged < 15) with miliary disease or positive blood culture, and those who moved out of the country within one year of initiating treatment.

⁵ Beginning in 2011, those who moved out of country during treatment are excluded from the denominator of those eligible for COT.

Note: Data for all years updated through June 5, 2015.

See Technical Notes for description of COT calculation.

See Surveillance Slides #30 and #31.

Data complete through 2012 only. See Technical Notes for details.

**Table 11. Tuberculosis Cases and Percentages in Persons with HIV Test Results¹ and with HIV Infection by Age Group:
United States, 1993–2014**

Year	Total No.	25–44 Years Old		All Ages		HIV Positive (%)	
		HIV Test Results		HIV Positive			
		No.	(%)	No.	(%)

2014	2,806	2,622	(93)	228	(9)	9,229 (89)	

¹ Includes persons with positive, negative, or indeterminate HIV test results and persons from California with co-diagnosis of TB and AIDS for the period 1993–2004, and those persons not dead at diagnosis. Rhode Island did not report HIV test results for years 1993–1997. HIV test results for Vermont are not included for years 2007–present. HIV test results for California are not included for years 2005–2010.

² California began reporting HIV test results to CDC in 2011

Note: Data for all years updated through June 5, 2015.
See Surveillance Slides #26 and #27.

												435	(4.5)

¹ Includes all cases in persons reported as alive at diagnosis and taking one or more TB drugs.

² In 2009 the moved variable was removed from the RVCT; see Technical Notes for details.

³ Died = died of any cause (not only TB).

⁴ Includes cases in persons reporting reason therapy stopped = Other, Missing, Unknown, or Moved (from 2010 on).

Note: Data for all years are updated through June 5, 2015.

Data complete through 2012 only. See Technical Notes for details.

Table 13. National Tuberculosis Genotyping Surveillance Coverage¹: United States, 2004–2014

Year	Reported TB Cases	Reported Culture Positive Cases	Cases with Genotype Result	Genotype Surveillance Coverage
	No.	No.	No.	(%)
2004	14,499	11,327	5,956	(52.6)
2005	14,063	10,956	7,500	(68.5)
2006	13,728	10,745	7,528	(70.1)
2007	13,282	10,426	8,431	(80.9)
2008	12,895	10,022	8,180	(81.6)
2009	11,523	8,884	7,714	(86.8)
2010	11,161	8,458	7,749	(91.6)
2011	10,510	8,086	7,616	(94.2)
2012	9,941	7,625	7,226	(94.8)
2013	9,565	7,367	7,044	(95.6)
2014	9,421	7,226	6,887	(95.3)

¹ Genotype surveillance coverage is defined as the percentage of all culture positive tuberculosis (TB) cases for which there was a genotyped isolate.

NOTE: This table reflects genotyping surveillance coverage for the 50 states and the District of Columbia; for genotyping surveillance coverage of the United States Affiliated Pacific Islands, please see Table 14.

See Surveillance Slide #33.

Table 14. National Tuberculosis Genotyping Surveillance Coverage¹: United States Affiliates², 2004–2014

Year	Reported TB Cases	Reported Culture Positive Cases	Cases with Genotype Result	Genotype Surveillance Coverage
	No.	No.	No.	(%)
2004	288	213	19	(8.9)
2005	388	237	95	(40.1)
2006	344	211	84	(39.8)
2007	527	181	85	(47.0)
2008	553	240	72	(30.0)
2009	534	237	206	(86.9)
2010	618	309	271	(87.7)
2011	462	229	191	(83.4)
2012	493	247	225	(91.1)
2013	413	217	197	(90.8)
2014	454	225	208	(92.4)

¹ Genotype surveillance coverage is defined as the percentage of all culture positive tuberculosis (TB) cases for which there was a genotyped isolate

² The United States affiliates include: American Samoa, Northern Mariana Islands, Federated States of Micronesia, Guam, Marshall Islands, Palau, Puerto Rico, and United States Virgin Islands.

Table 15. Genotyped Tuberculosis Cases with *Mycobacterium bovis*¹ by Origin of Birth: United States, 2004–2014

Year	Total Genotyped Cases	<i>Mycobacterium bovis</i> cases					
		Total		U.S.-born		Foreign-born	
	No.	No. ²	(%)	No.	(%) ³	No.	(%) ³
2004	5,956	73	(1.2)	23	(31.5)	50	(68.5)
2005	7,500	81	(1.1)	23	(28.4)	58	(71.6)
2006	7,528	116	(1.5)	25	(21.6)	90	(77.6)
2007	8,431	112	(1.3)	17	(15.2)	94	(83.9)
2008	8,180	129	(1.6)	29	(22.5)	100	(77.5)
2009	7,714	113	(1.5)	27	(23.9)	86	(76.1)
2010	7,749	108	(1.4)	20	(18.5)	88	(81.5)
2011	7,616	117	(1.5)	30	(25.6)	87	(74.4)
2012	7,226	109	(1.5)	18	(16.5)	91	(83.5)
2013	7,044	96	(1.4)	22	(22.9)	74	(77.1)
2014	6,887	107	(1.6)	24	(22.4)	83	(77.6)

¹ *M. bovis* cases were defined predominantly by spoligotyping results with missing spacers 3, 9, 16, and 39–43. Data exclude 107 cases of Bacillus Calmette-Guérin (BCG) *M. bovis*, which have x, y or z in the second MIRU position. Please see technical notes for details regarding changes in the *M. bovis* definition, which result in a 13.9% reduction in the average of annual *M. bovis* case counts (n=105) compared to average annual counts that would have been reported without these changes (n=122).

² This column reports all genotyped *M. bovis* cases, including those where origin of birth is unknown.

³ Denominator is all *M. bovis* cases.

¹Persons of Latino origin may be of any race or multiple race.

²Indicates two or more races reported for a person.

Note: Denominators for computing 2014 case rates were obtained from the U.S. Census Monthly Postcensal Resident Population, by single year of age, sex, race, and Hispanic origin (<http://www.census.gov/popest/datasets/national/asrh/2014/files/NC-EST2014-ALLDATA-R-File10.csv>) (accessed June 25, 2015).

Case counts for race categories (American Indian or Alaska Native, Asian, Black or African American, Native Hawaiian or Other Pacific Islander, and White) are mutually exclusive and do not include persons of Hispanic ethnicity or multiple race. Multiple Race does not include persons of Hispanic ethnicity.
See Technical Notes.

See Surveillance Slides #9 and #11.

¹Includes the number of risk factors reported (which may be more than one per case) and the number of cases with no information on additional risk factors. The sum of risk factors is greater than the total number of cases because more than one risk factor may be selected per case.

²Excludes TB risk factor information for 18 cases with unknown origin

³Persons of Hispanic or Latino origin may be of any race or multiple race.

⁴Indicates two or more races reported for a person.

Note: Case counts for race categories (American Indian or Alaska Native, Black or African American, Native Hawaiian or Other Pacific Islander, and White) are mutually exclusive and do not include persons of Hispanic ethnicity or multiple race. Multiple Race does not include persons of Hispanic ethnicity.

¹ GENType clusters have two or more cases with matching spoligotype and 24-locus mycobacterial interspersed repetitive unit-variable tandem repeat type within a county during the specified 3-year time period.

² Alert levels are based on a log-likelihood ratio (LLR), which calculates the geographic concentration of a genotype in a county compared to the rest of the county during a 3-year period.

³ There were 4,544 cases in 1,494 alerted clusters; 908 cases were in 93 (6.2%) high alert clusters, and 2,600 cases were in 338 (22.6%) medium alert clusters, and 2,600 cases were in 1,063 (71.2%) non-alert clusters.

Note: Case counts for race categories (American Indian or Alaska Native, Asian, Black or African American, Native Hawaiian or Other Pacific Islander, and White) are mutually exclusive and do not include persons of Hispanic ethnicity or multiple race. Multiple Race does not include persons of Hispanic ethnicity.
See Surveillance Slide #36

Table 23. Tuberculosis Cases by Cluster Status¹: United States, 2012–2014

Cluster Status	Cases	
	No.	(%)
Total	21,075	(100.0)
Unique ²	16,531	(78.4)
Clustered ³	4,544	(21.6)

¹ Cluster status indicates whether a case is unique or clustered within a county for cases with a valid GENType.

² A unique case is a case with a GENType (spoligotype and 24 locus mycobacterial interspersed repetitive unit-variable tandem repeat type) that does not match any other case in that county during the specified three-year time period.

³ Clustered cases are defined as two or more cases with same GENType within a county during the specified 3-year time period.

See Surveillance Slide #34

Table 24. Tuberculosis Cases and Clusters by Cluster Size¹: United States, 2012–2014

Cluster Size	Clusters		Cases ²	
	No.	(%) ³	No.	(%) ⁴
Total	1,494	(100.0)	4,544	(100.0)
2 case cluster	968	64.8	1936	42.6
3 case cluster	262	17.5	786	17.3
4 case cluster	113	7.6	452	9.9
5 case cluster	55	3.7	275	6.1
6 case cluster	24	1.6	144	3.2
7 case cluster	16	1.1	112	2.5
8 case cluster	11	0.7	88	1.9
9 case cluster	10	0.7	90	2.0
≥10 case cluster	35	2.3	661	14.5

¹ Clusters have two or more cases with matching spoligotype and 24-locus mycobacterial interspersed repetitive unit-variable number tandem repeat type (GENTType) within a county during the specified 3-year time period.

² Cases with matching spoligotype and 24-locus mycobacterial interspersed repetitive unit-variable number tandem repeat type (GENTType) are members of a cluster within a county during the specified 3-year time period.

³ Denominator is total number of clusters

⁴ Denominator is total number of cases

See Surveillance Slide #35.

¹ GENType is defined as a unique combination of spoligotype and 24-locus mycobacterial interspersed repetitive unit-variable number tandem repeat (MIRU-VNTR) type.

² PCRTyp^e is defined as a unique combination of spoligotype and 12-locus MIRU-VNTR; every GENType has a corresponding PCRTyp^e.

³ Among 21,157 cases with GENTypes during 2012–2014.

⁴ This table reflects common GENTypes for the 50 states and the District of Columbia; for common GENTypes in the United States Affiliated Pacific Islands, please see Table 26.

Table 26. Five Most Frequently Reported GENTypes¹ Among Genotyped Tuberculosis Cases: United States Affiliates², 2012–2014

¹ GENType is defined as a unique combination of spoligotype and 24-locus mycobacterial interspersed repetitive unit-variable number tandem repeat (MIRU-VNTR) type.

²The United States affiliates include: American Samoa, Northern Mariana Islands, Federated States of Micronesia, Guam, Marshall Islands, Palau, Puerto Rico, and United States Virgin Islands.

³ PCRTyp is defined as a unique combination of spoligotype and 12-locus MIRU-VNTR; every GENType has a corresponding PCRTyp.

⁴ Among culture-positive genotyped TB cases during 2012–2014 (n=630).

2012

Table 27. Tuberculosis Cases and Percentages by Reason Tuberculosis Therapy Stopped and Type of Move: United States, 2012

Type of Move	Total Cases	Completed Therapy		Adverse Event	Lost		Refused	Died		Other ⁵	Unknown
	No.	No.	(%)	No.	(%)	No.	(%)	No.	(%)	No.	(%)
Moved in state ¹	303	256	(84.5)	1	(0.3)	9	(3.0)	2	(0.7)	14	(4.6)
Moved out of state ²	287	220	(76.7)	1	(0.3)	18	(6.3)	3	(1.0)	6	(2.1)
Moved out of country ³	415	163	(39.3)	0	(0.0)	26	(6.3)	0	(0.0)	11	(2.7)
Did not move ⁴	8646	7752	(89.7)	29	(0.3)	68	(0.8)	51	(0.6)	566	(6.5)
										46	(0.5)
										134	(1.5)

¹ Includes patients who were alive at diagnosis, started on treatment, and moved in state.

² Includes patients who were alive at diagnosis, started on treatment, and moved out of state.

³ Includes patients who were alive at diagnosis, started on treatment, and moved out of the country; transnational referrals were provided for 282 (68.0%) TB patients who moved out of the country.

⁴ Includes patients who were alive at diagnosis, started on treatment, and did not indicate having moved.

⁵ Therapy was discontinued for a known reason other than those listed (e.g. patient moved outside the U.S., or patient moved from state A to state B, and though state A notified state B, state B never followed up).

Note: There may be differences in the way jurisdictions determine treatment completion for patients who moved out of the country; some reporting jurisdictions may be classifying all patients who moved out of the country as 'other' for reason therapy stopped.

Table 28. Deaths Prior to Tuberculosis Diagnosis or During Tuberculosis Therapy by Age Group: United States, 2012

Age Group	Total		Dead at Diagnosis			Died During Therapy ¹				
	Total deaths reported	Deaths related to TB disease or therapy ²	Total dead at diagnosis	TB a cause of death	TB not a cause of death	Unknown/ Missing	Total died during therapy	Related to TB therapy/disease ³	Unrelated to TB therapy/disease	Unknown/ Missing

¹ Among patients alive at diagnosis. Excludes 13 patients who died during therapy but did not start on therapy or unknown whether or not therapy was started.

² Includes patients who were dead at diagnosis or died during therapy, for which TB or TB therapy was indicated as a cause of death.

³ Eight patient deaths during therapy were related to TB therapy.

Note: Ellipses indicate data not available.

¹ Persons of Hispanic origin may be of any race or multiple race.

² Indicates two or more races reported for a person.

³ Not included in U.S. totals.

Note: Case counts for race categories (American Indian or Alaska Native, Asian, Black or African American, Native Hawaiian or Other Pacific Islander, and White) are mutually exclusive and do not include persons of Hispanic ethnicity or multiple race. Multiple Race does not include persons of Hispanic ethnicity. See Technical Notes.

¹ Includes persons born outside the United States, American Samoa, the Federated States of Micronesia, Guam, the Republic of the Marshall Islands, Midway Island, the Commonwealth of the Northern Mariana Islands, Puerto Rico, the Republic of Palau, the U.S. Virgin Islands, and U.S. minor outlying and Pacific Islands.

² Other immigration status includes (but is not limited to) foreign-born persons who were not required to obtain a visa or persons with no official immigration status (ie, undocumented).

³ Immigration status is not applicable to persons who were born in one of the U.S. territories, U.S. island areas, or U.S. outlying areas.

⁴ Excludes New York City.

Note: Ellipses indicate data are not available.

¹Includes cases with pulmonary listed as the only site of disease.

²Includes cases with pleural, lymphatic, bone and/or joint, meningeal, peritoneal, genitourinary, or other site, excluding pulmonary, listed as site of disease.

³Includes cases with evidence of miliary disease.

⁴Not included in U.S. totals.

Note: 14 cases had missing and/or unknown site of disease.

U.S. Virgin Islands ⁴		

¹Includes the number of risk factors reported (which may be more than one per case) and the number of cases with no information on additional risk factors. The sum of risk factors is greater than the total number of cases because more than one risk factor may be selected per case.

²None of the options for additional risk factors was selected.

³Excludes New York City

⁴Not included in U.S. totals.

¹ Resident of long-term care facility at time of TB diagnosis. Percentage based on 52 reporting areas (50 states, New York City, and the District of Columbia). Counts and percentages shown only for reporting areas with information reported for ≥75% of cases.

² Percent of those with known status.

³ Excludes New York City.

⁴ Not included in U.S. totals.

Note: Ellipses indicate data not available.

¹Genotype surveillance coverage is defined as the percentage of all culture positive tuberculosis (TB) cases for which there was a genotyped isolate.

²National TB Performance Indicator goal for national TB genotyping surveillance coverage is 94%.

³Not included in U.S. totals.

See Technical Notes.

¹ Clusters are two or more cases with matching spoligotype and 24-locus mycobacterial interspersed repetitive unit-variable number tandem repeat type (GENType) within a county during the specified 3-year time period (Total number of clusters from 2012–2014=1,494).

² Genotype surveillance coverage is defined as the percentage of all culture positive tuberculosis (TB) cases for which there was a genotyped isolate.

Note: Ellipses indicate data not available.

See Technical Notes.

¹Most recent year for which data are available.

²Number of cases in persons alive at diagnosis, with an initial regimen of one or more drugs prescribed. Percentage for U.S. based on 52 reporting areas (50 states, New York City, and the District of Columbia).

³ Died = Died of any cause.

⁴ Includes cases reported as Other, Missing, or Unknown.

⁵ Excludes New York City.

⁶ Not included in U.S. totals.

Note: Ellipses indicate data not available.

¹ Percentages shown only for reporting areas with information reported for ≥90% of cases, and indicate the percentage of those who completed therapy within 1 year.

² Most recent year for which data are available.

³ Therapy < 1 year indicated in persons alive at diagnosis with an initial regimen of one or more drugs prescribed, who did not die within one year of initiating therapy. Excludes persons with initial isolate rifampin resistant, or patient with bone and joint disease, meningeal disease or disease of the central nervous system, or pediatric patient (aged < 15) with military disease or positive blood culture, and those who moved out of the country within one year of initiating treatment.

⁴ Persons of Hispanic or Latino origin may be of any race.

⁵ Excludes New York City.

⁶ Not included in U.S. totals.

Note: Case counts and percentage for race categories do not include persons of Hispanic ethnicity. Ellipses indicate data not available. See Technical Notes for description of Completion of Therapy calculation (page 9).

¹ Most recent year for which data are available.

² Initial isolate susceptible to rifampin (n=5,973) or susceptibility unknown (n=111); culture negative (n=1,722); culture status unknown (n=317).

³ Number of cases in persons alive at diagnosis, with an initial regimen of one or more drugs prescribed, who did not die during therapy. Percentage for U.S. based on 52 reporting areas (50 states, New York City, and the District of Columbia). Percentages shown only for reporting areas with information reported for ≥90% of cases.

⁴ Therapy < 1 year indicated in persons alive at diagnosis with an initial regimen of one or more drugs prescribed, who did not die within one year of initiating therapy. Excludes persons with initial isolate rifampin resistant, or patient with bone and joint disease, meningeal disease or disease of the central nervous system, or pediatric patient (aged < 15) with miliary disease or positive blood culture, and those who moved out of the country within one year of initiating treatment.

⁵ Initial isolate rifampin resistant, or patient with meningeal disease, or pediatric patient (aged <15) with miliary disease or positive blood culture.

⁶ Excludes New York City.

⁷ Not included in U.S. totals.

Note: Ellipses indicate data not available. See Technical Notes for description of Completion of Therapy calculation (page 9).

Table 61. Tuberculosis Cases and Percentages in Persons Completing Therapy for Whom Therapy Was Indicated for One Year or Less: Reporting Areas, 2008–2012¹

¹ Persons of Hispanic or Latino origin may be of any race or multiple race.

² Indicates two or more races reported for a person.

Note: Case counts for race categories (American Indian or Alaska Native, Asian, Black or African American, Native Hawaiian or Other Pacific Islander, and White) are mutually exclusive and do not include persons of Hispanic ethnicity or multiple race. Multiple Race does not include persons of Hispanic ethnicity.

See Technical Notes for definition of MSA and Hispanic ethnicity and non-Hispanic race.

Surveillance Slide Set

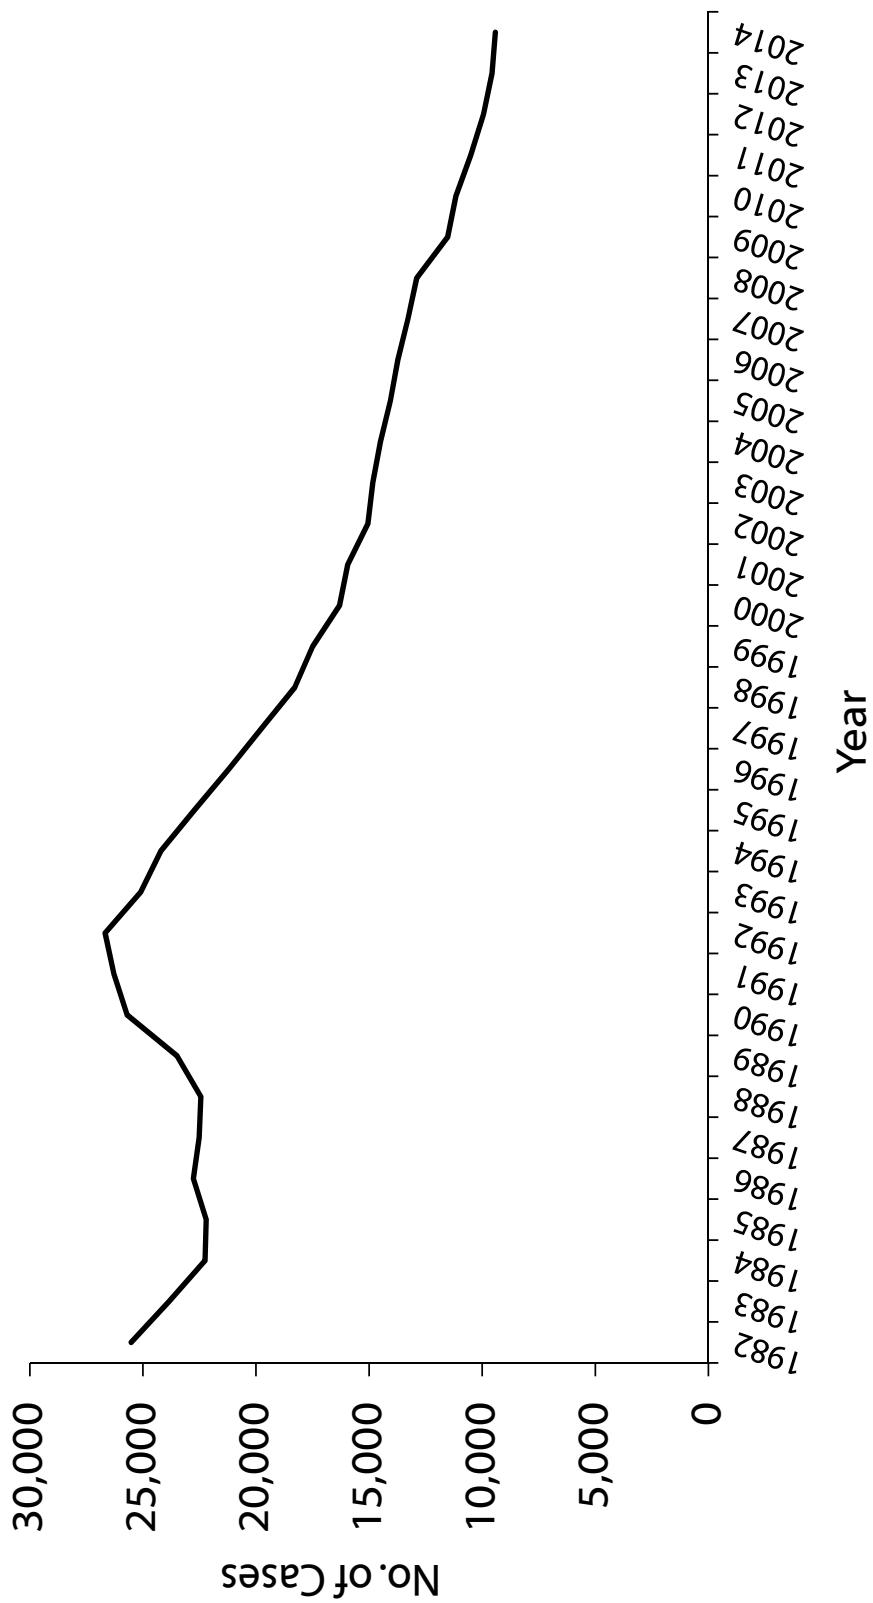

2014

Tuberculosis in the United States

National Tuberculosis Surveillance System
Highlights from 2014

Surveillance Slide #2

Reported TB Cases United States, 1982–2014*

*Updated as of June 5, 2015.

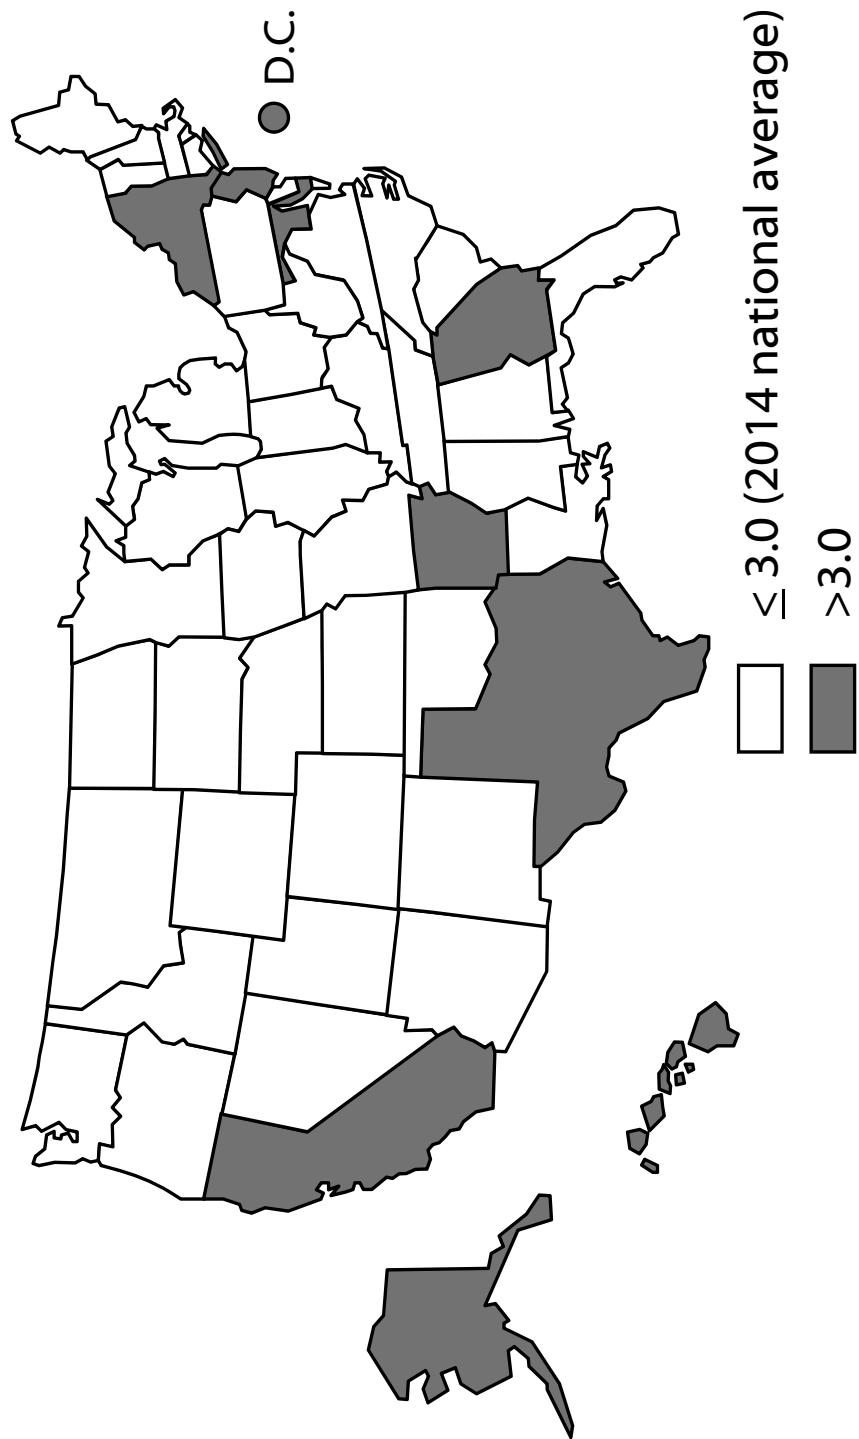

TB Morbidity United States, 2009–2014

Year	No.	Rate*
2009	11,523	3.8
2010	11,161	3.6
2011	10,510	3.4
2012	9,941	3.2
2013	9,565	3.0
2014	9,421	3.0

*Cases per 100,000. Updated as of June 5, 2015.

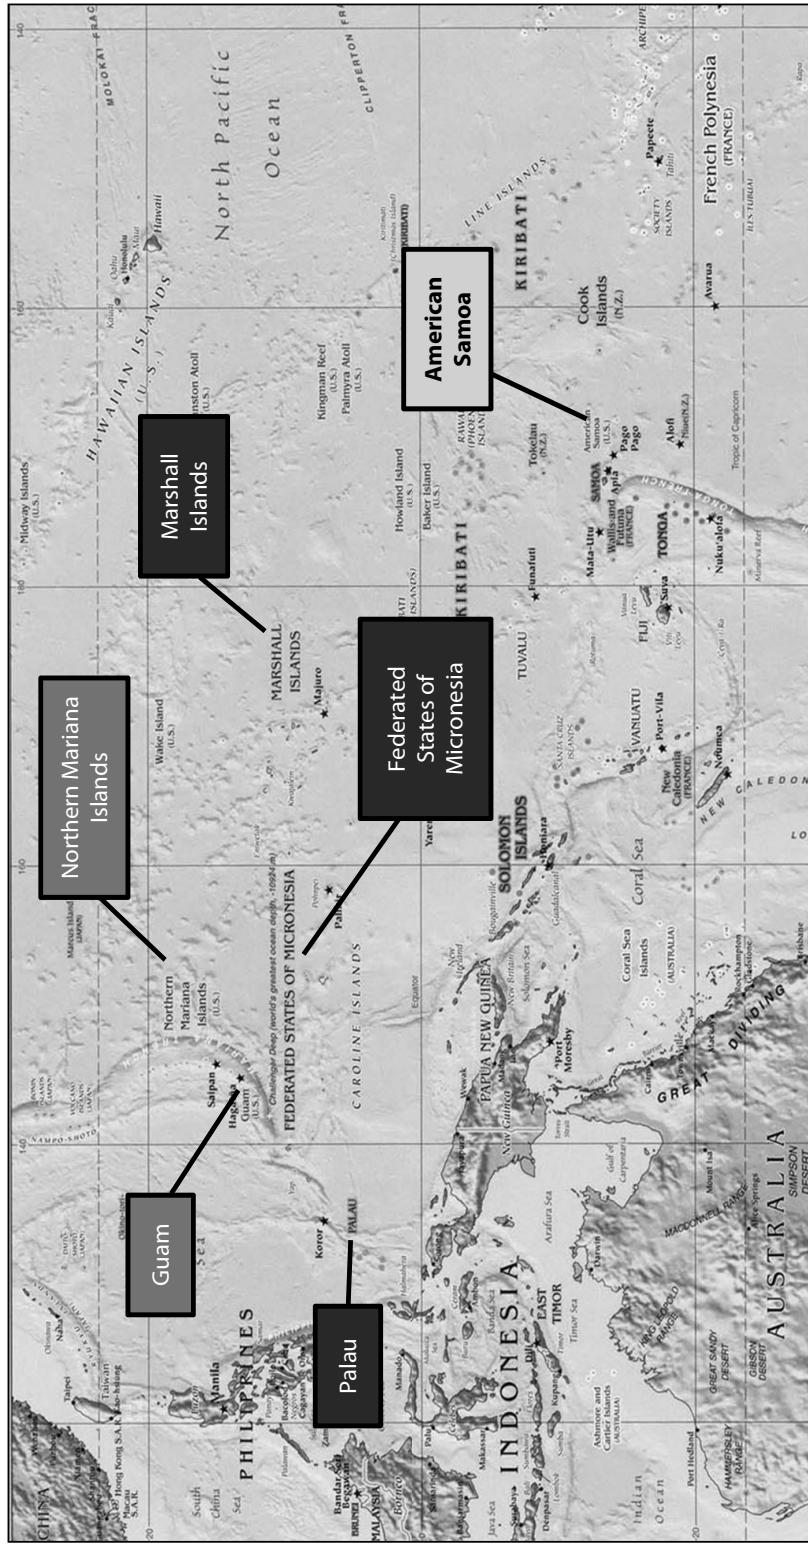

Surveillance Slide #4

TB Case Rates,* United States, 2014

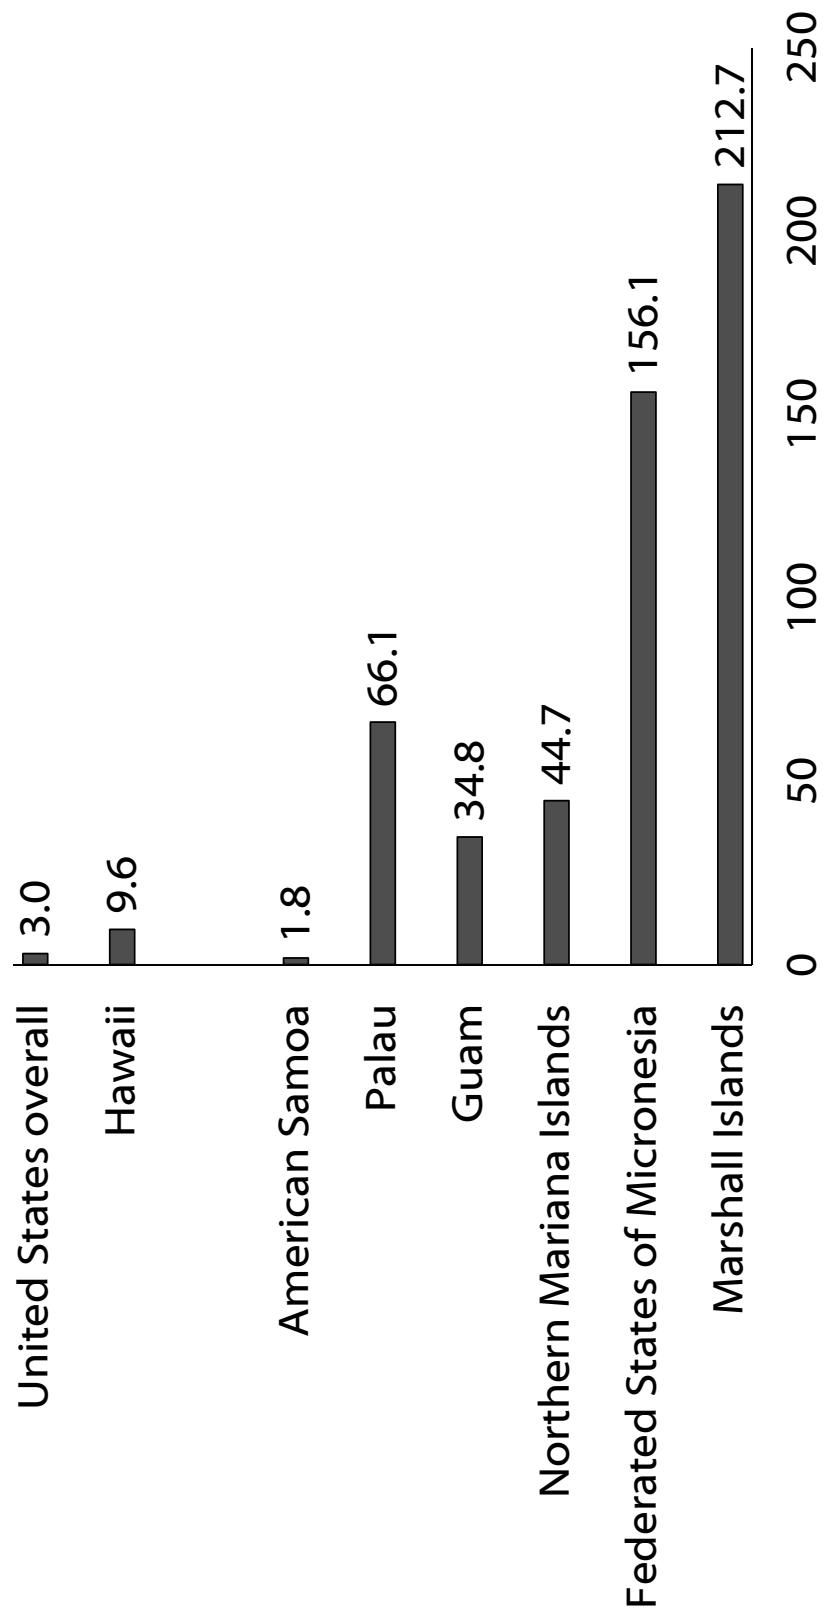

Surveillance Slide #5

Map of U.S.-Affiliated Pacific Islands by TB Case Rates,* 2014

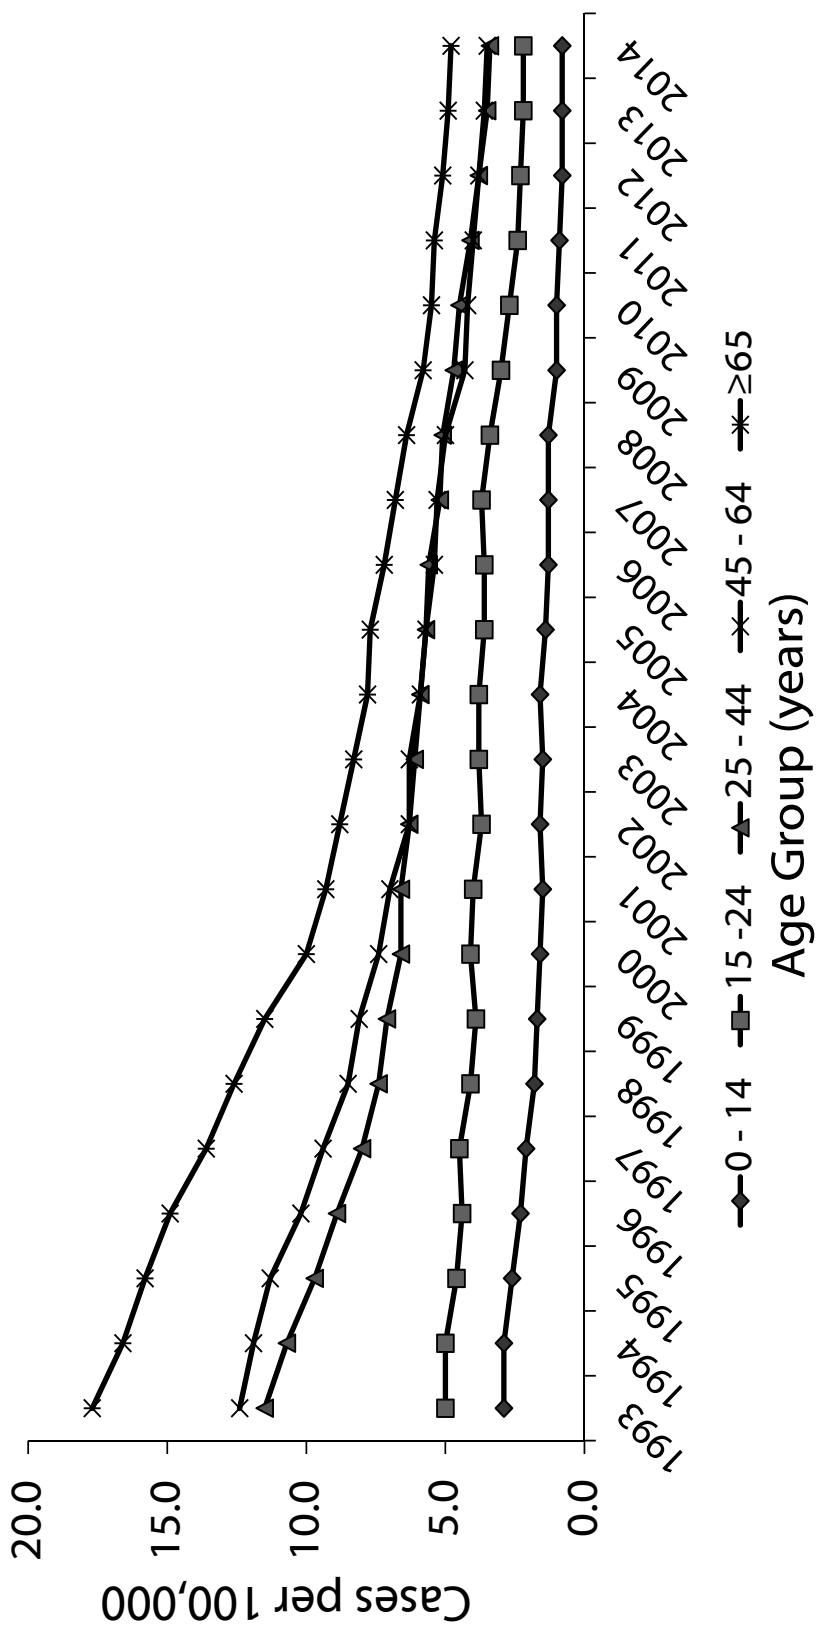

*Cases per 100,000

TB Case Rates,* U.S.-Affiliated Pacific Islands, 2014

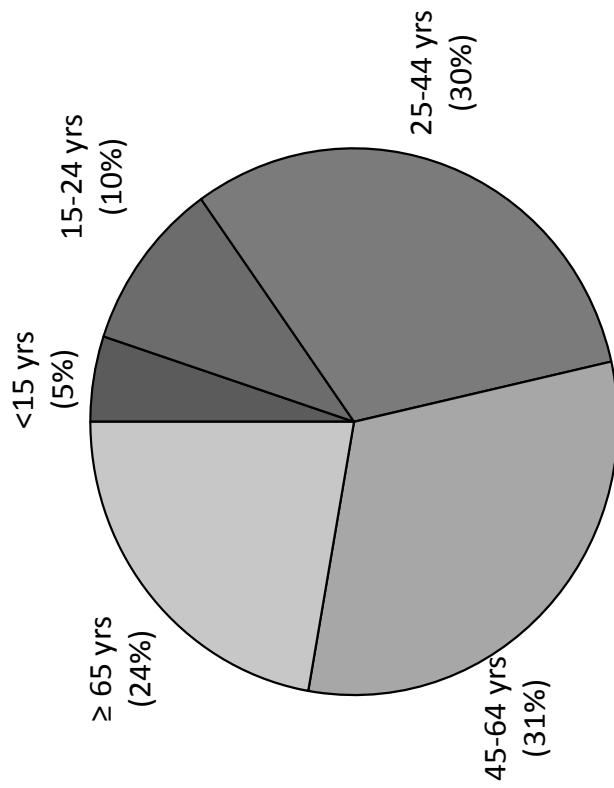

*Cases per 100,000

TB Case Rates* by Age Group United States, 1993–2014

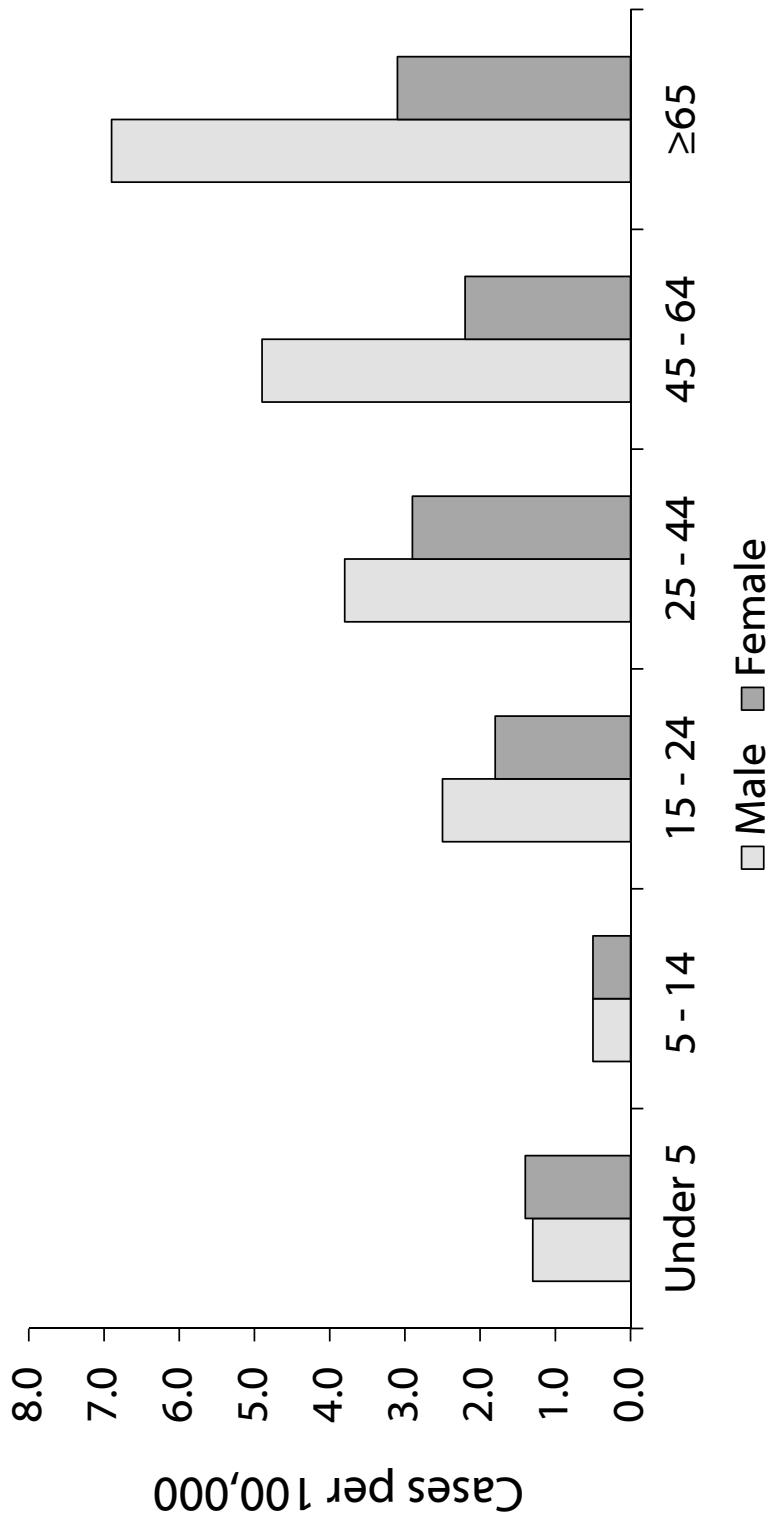

* Updated as of June 5, 2015.

**Reported TB Cases by Age Group,
United States, 2014**

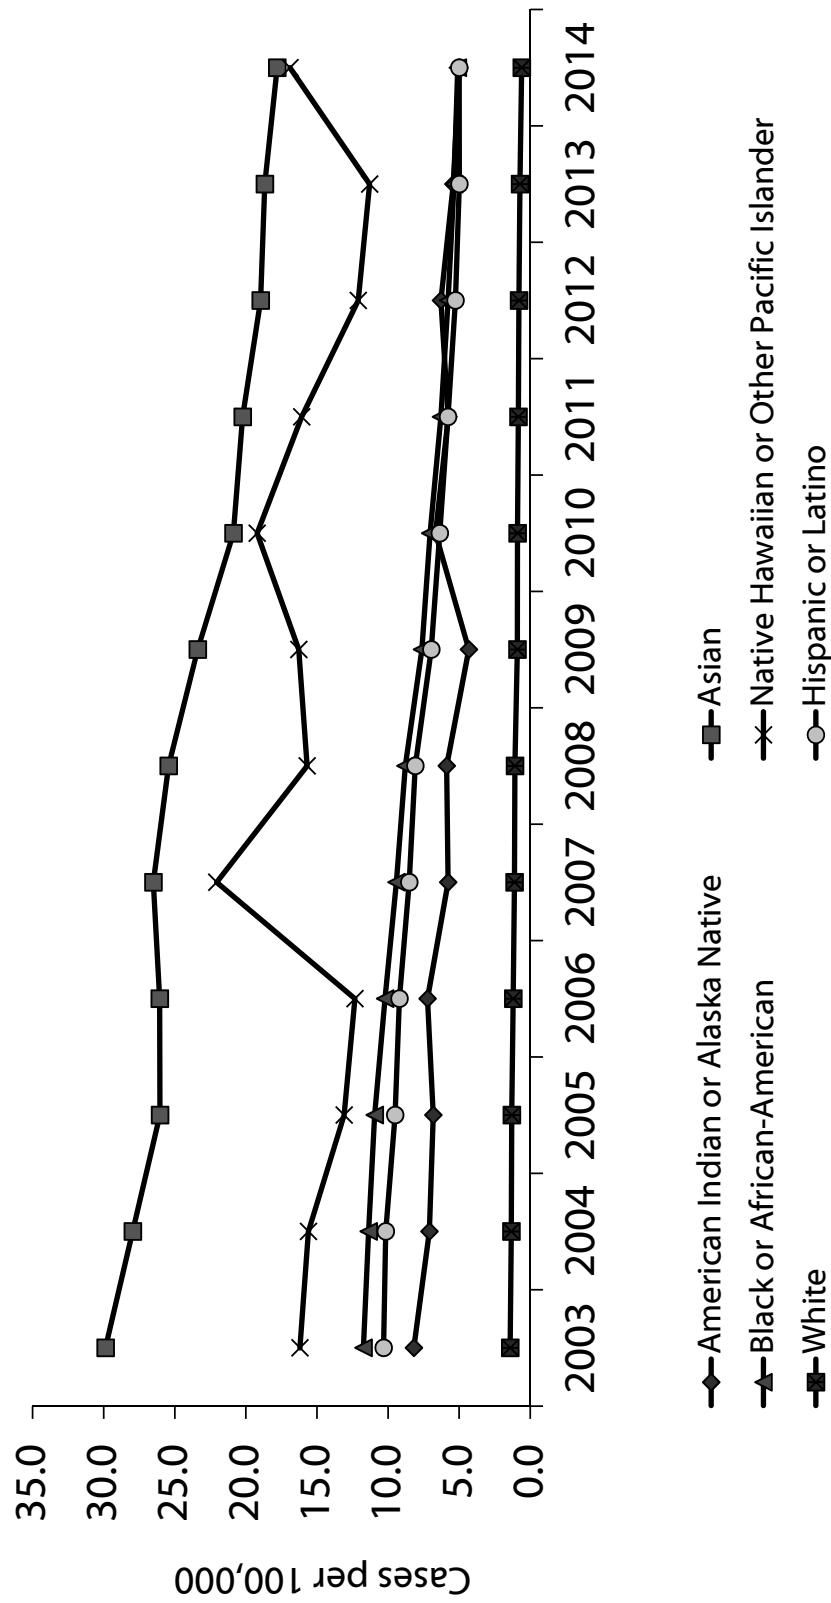

TB Case Rates by Age Group and Sex, United States, 2014

Surveillance Slide #10

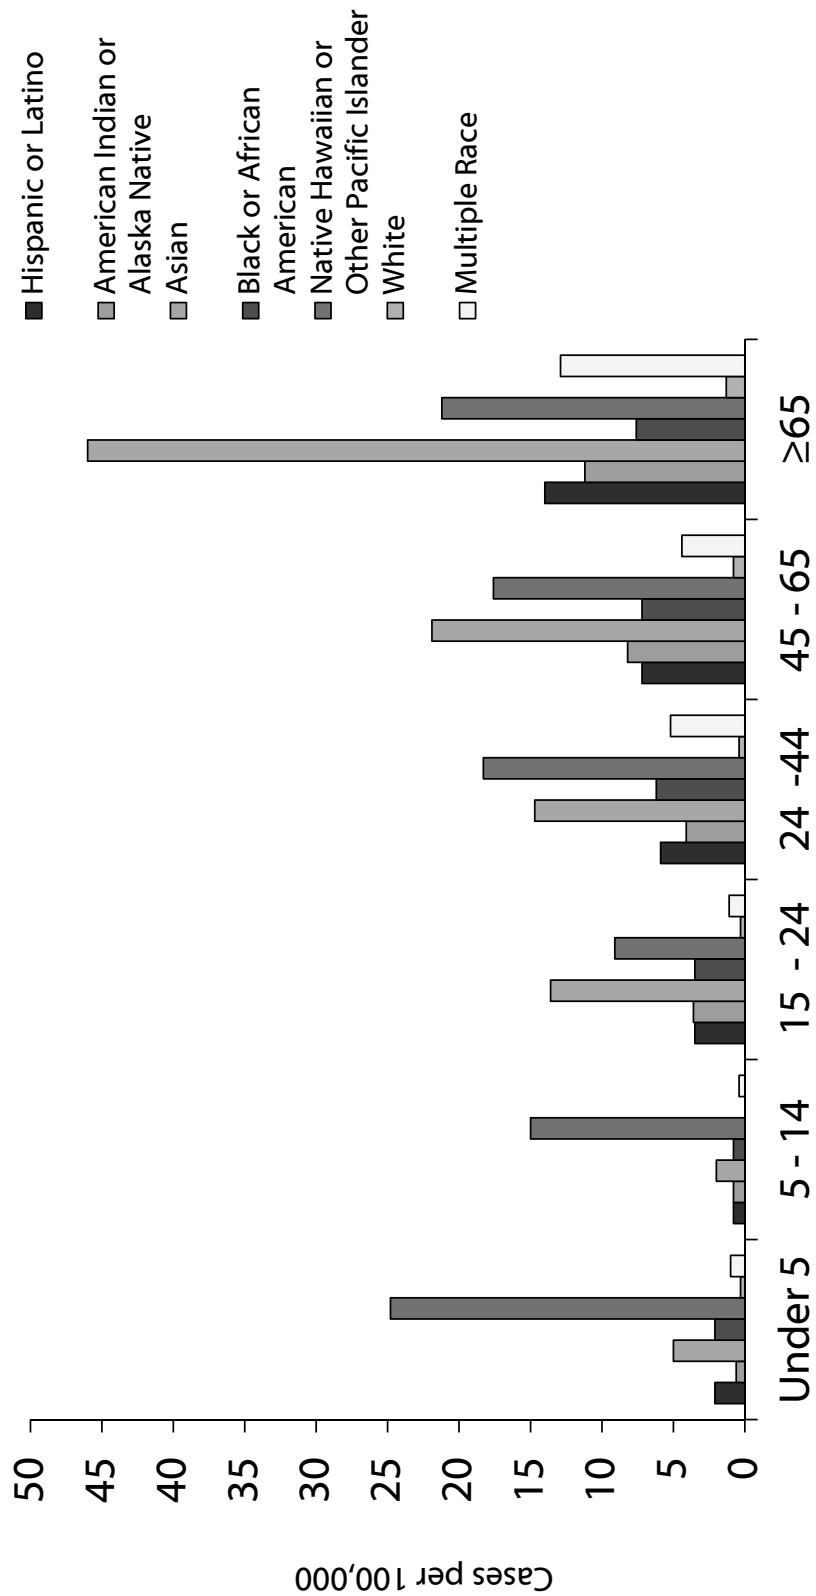

TB Case Rates by Race/Ethnicity, United States, 2003-2014**

*All races are non-Hispanic.
**Updated as of June 5, 2015.

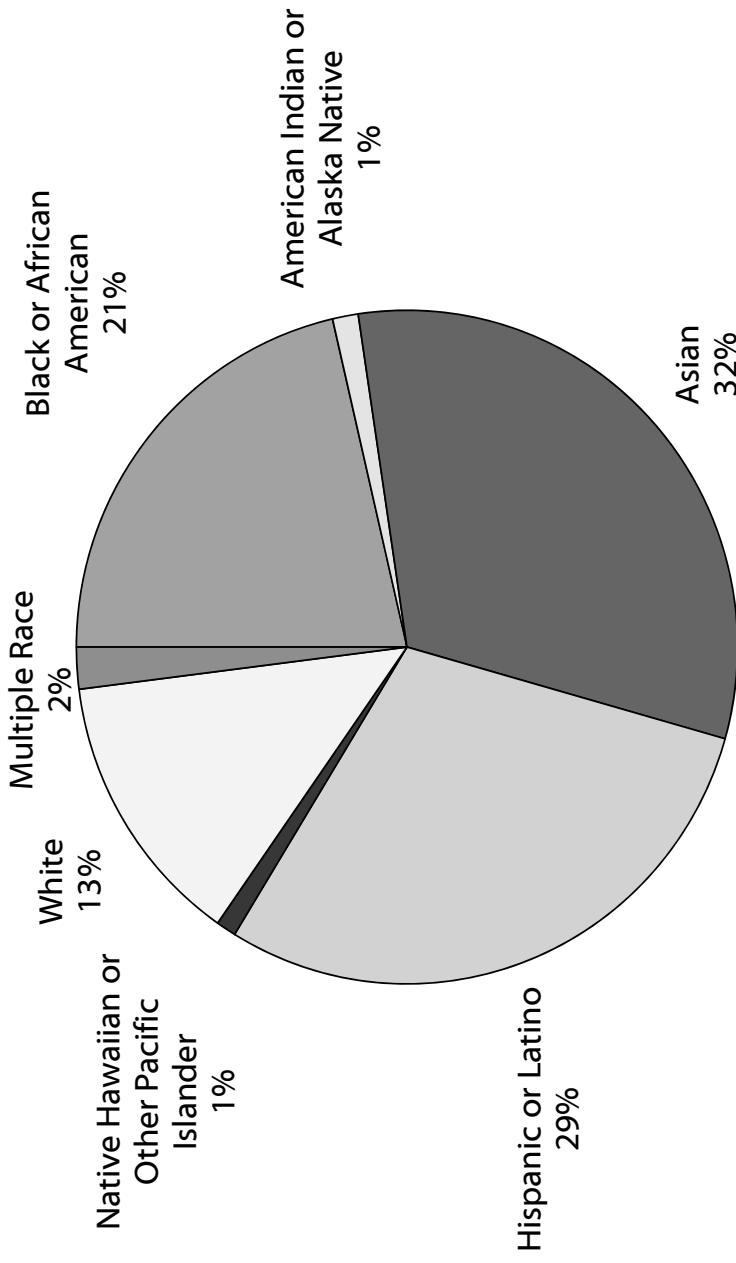

Surveillance Slide #11

TB Case Rates by Age Group and Race/Ethnicity,* United States, 2014

*All races are non-Hispanic. Multiple Race indicates two or more races reported for a person. Does not include persons of Hispanic or Latino origin.

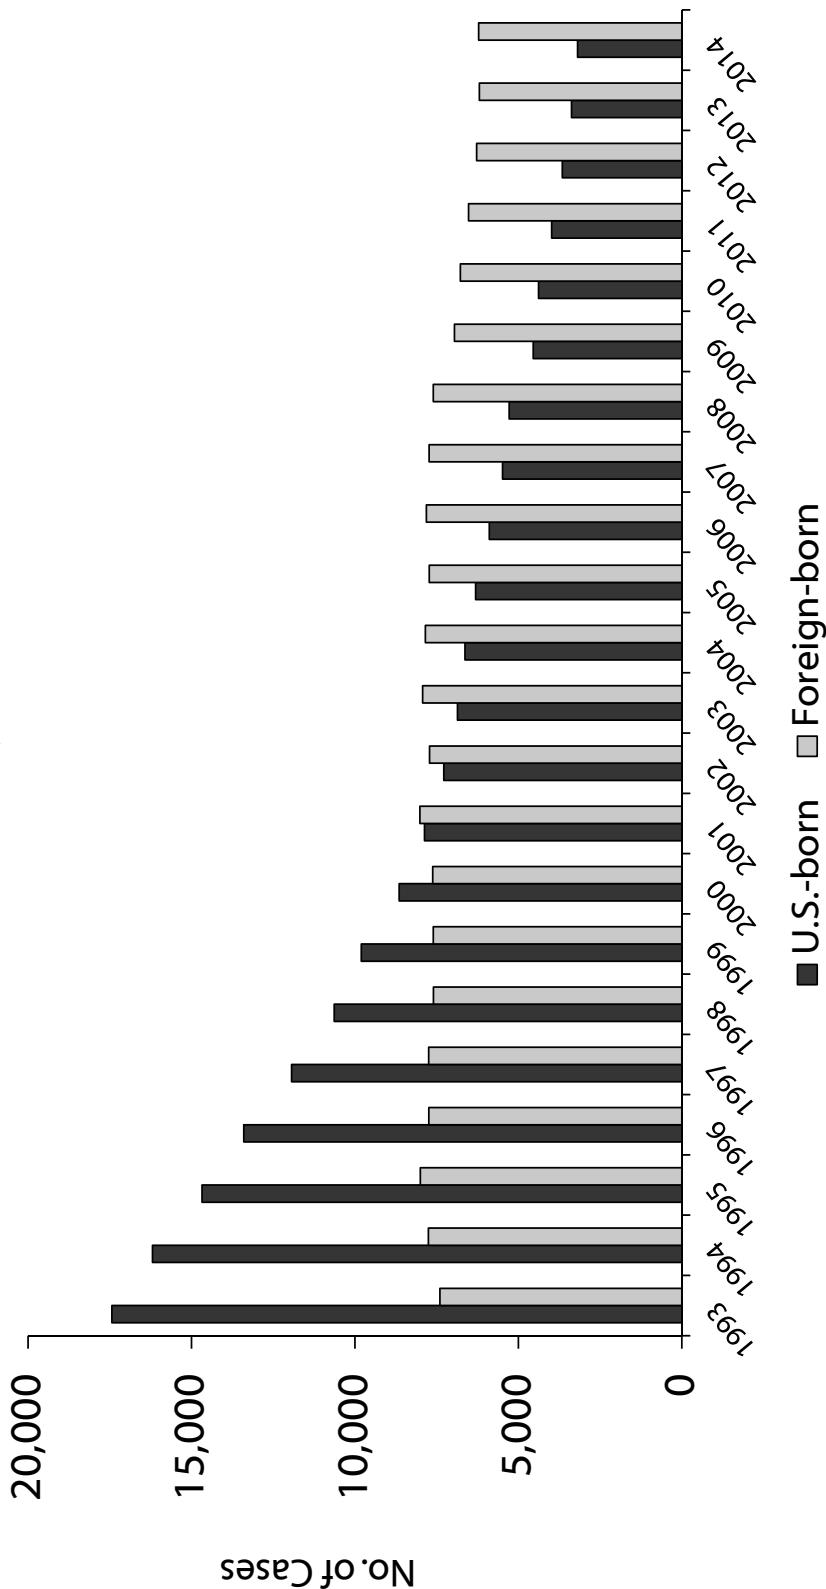

Reported TB Cases by Race/Ethnicity,* United States, 2014

*All races are non-Hispanic. Multiple Race indicates two or more races reported for a person. Does not include persons of Hispanic or Latino origin.

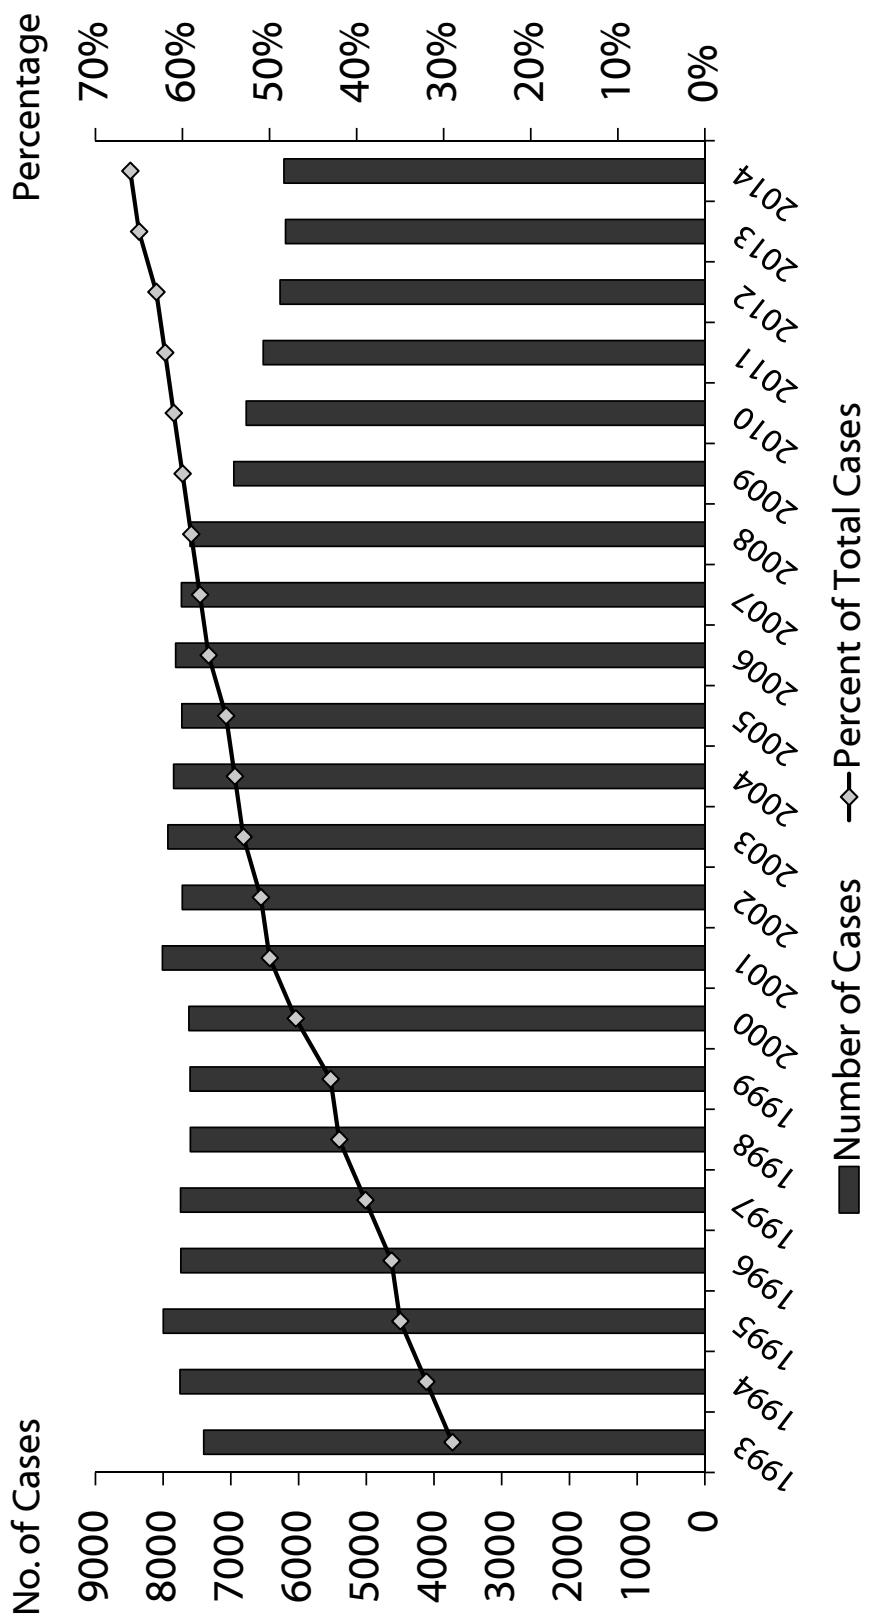

Surveillance Slide #13

Number of TB Cases in U.S.-born vs. Foreign-born Persons, United States, 1993–2014*

*Updated as of June 5, 2015.

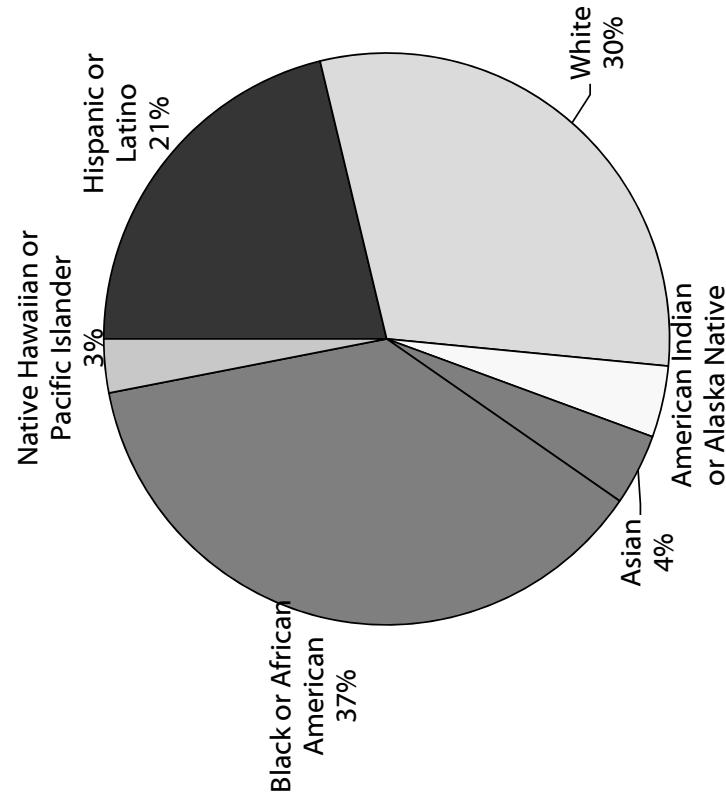

Trends in TB Cases in Foreign-born Persons, United States, 1993 - 2014*

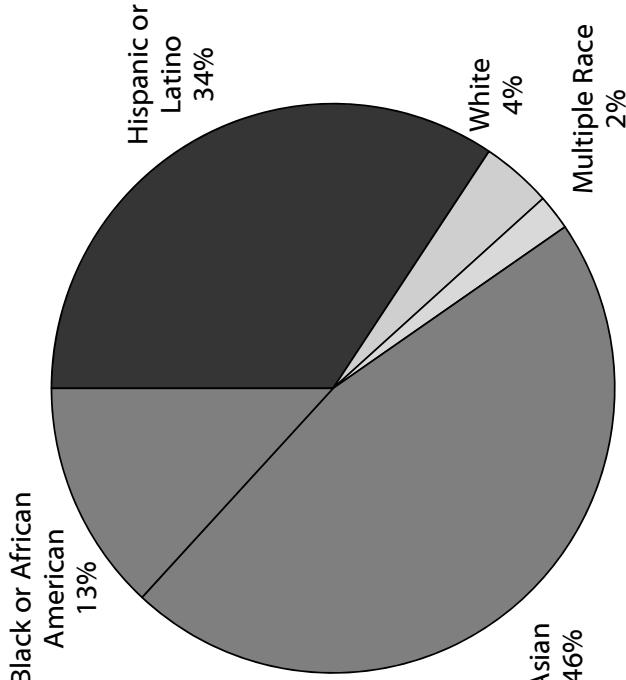

*Updated as of June 5, 2015.

Reported TB Cases by Origin and Race/Ethnicity, United States, 2014

U.S.-born*

Foreign-born**

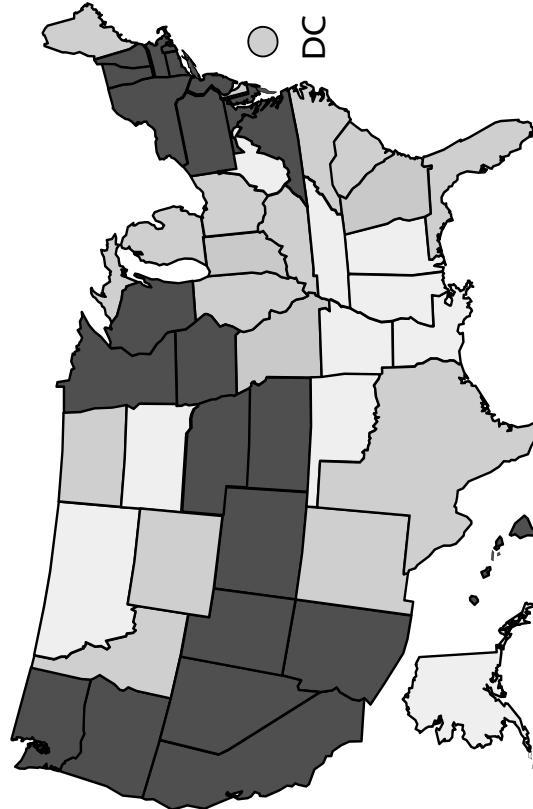

*All races are non-Hispanic. Persons reporting two or more races accounted for 1% of all cases for U.S. born cases and are not shown.

** American Indian or Alaska Native and Native Hawaiian or Other Pacific Islander accounted for less than 1% of foreign-born cases and are not shown. Multiple Race indicates two or more races reported for a person. Does not include persons of Hispanic or Latino origin.

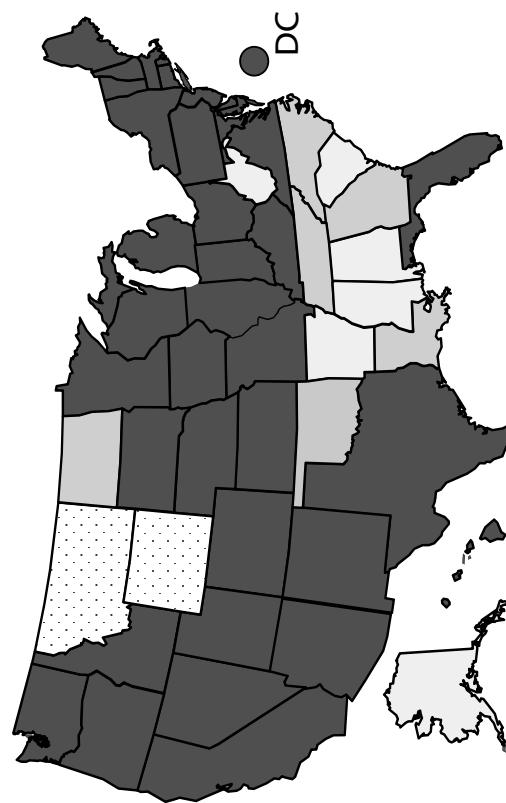

Percentage of TB Cases Among Foreign-born Persons, United States*

2004

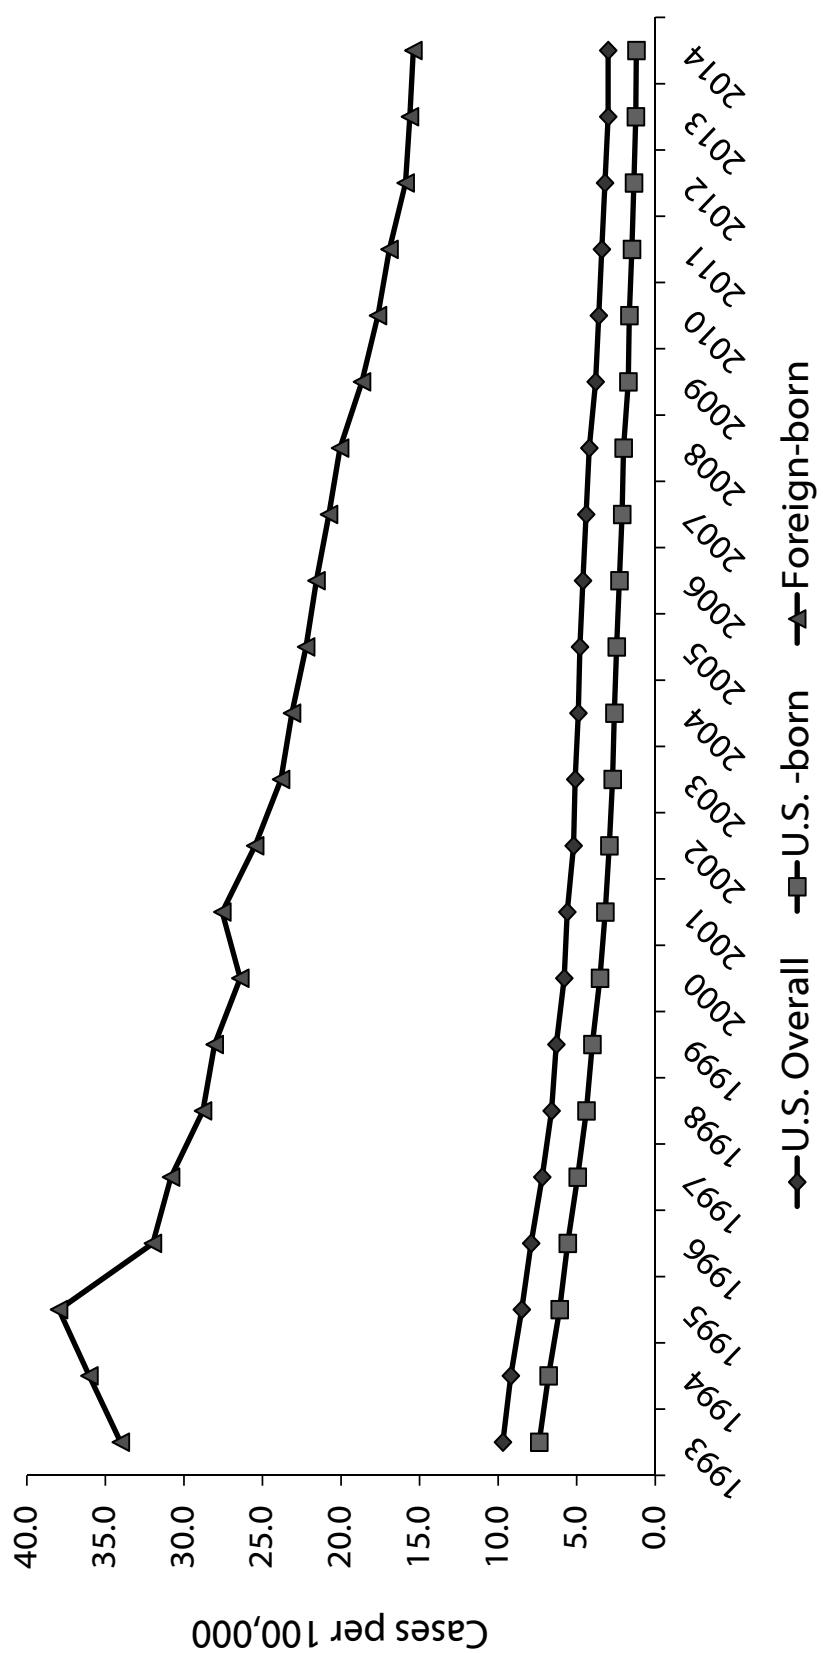

$\geq 50\%$
 $25\%-49\%$
 $<25\%$
No cases

2014

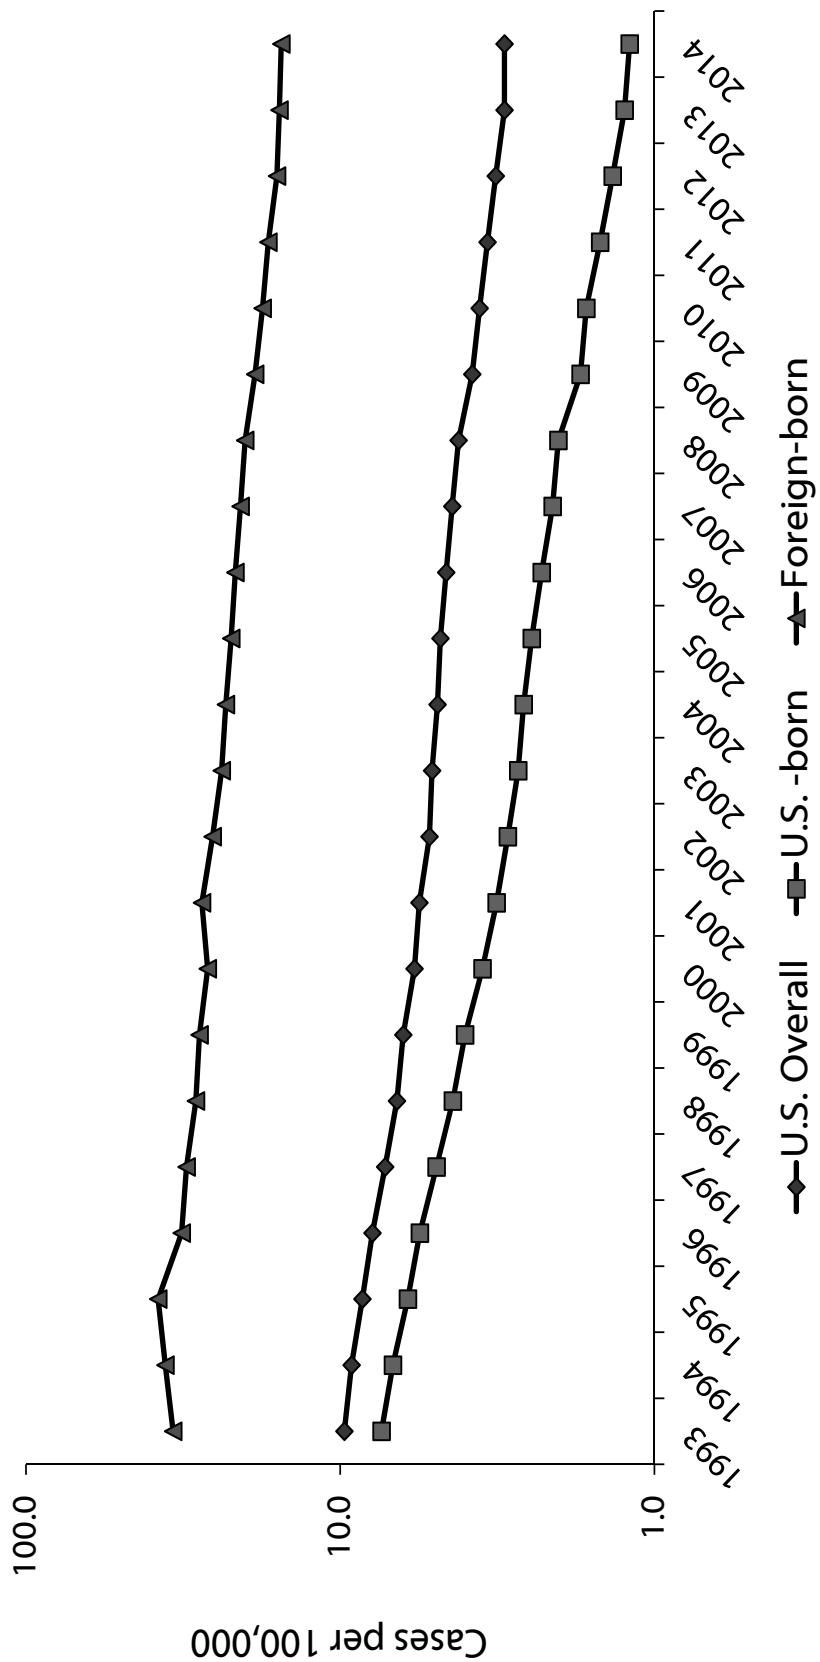

*Updated as of June 5, 2015.

TB Case Rates in U.S.-born vs. Foreign-born Persons, United States, 1993 – 2014*

*Updated as of June 5, 2015.

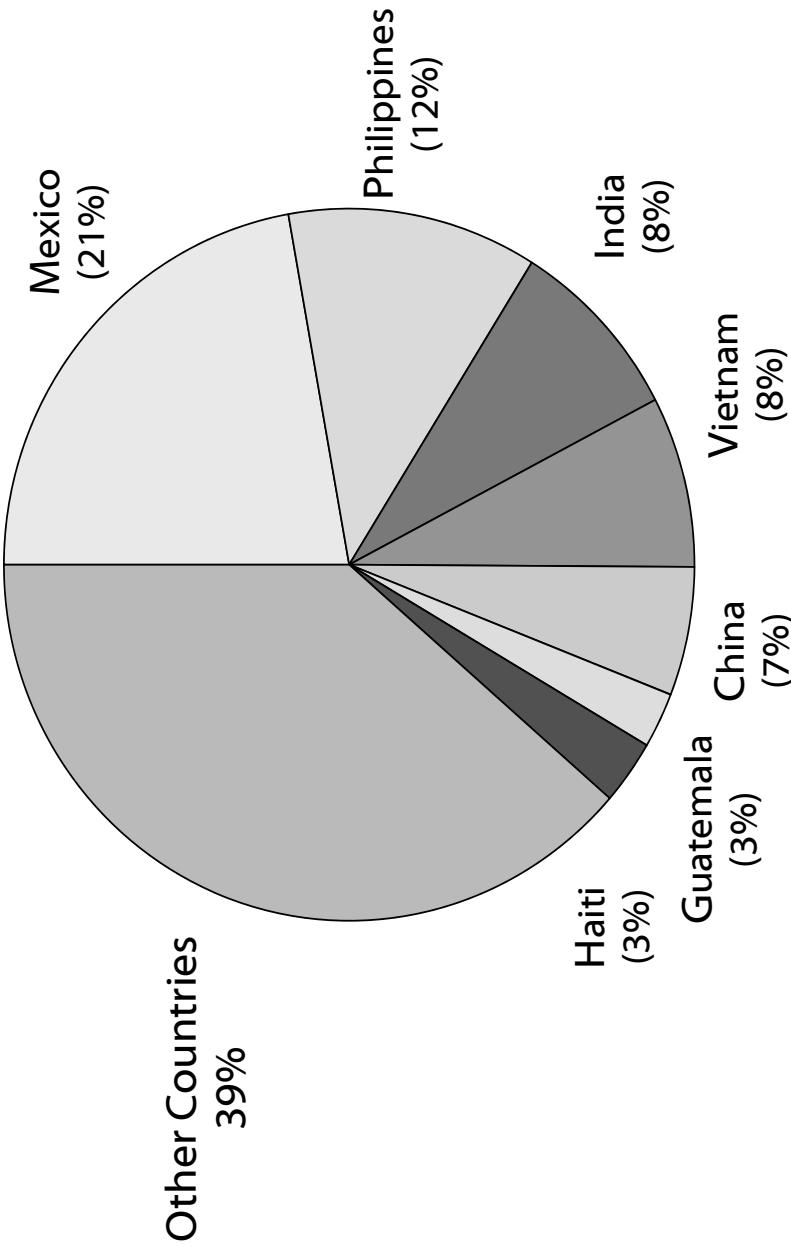

TB Case Rates in U.S.-born vs. Foreign-born Persons, United States,* 1993 - 2014**

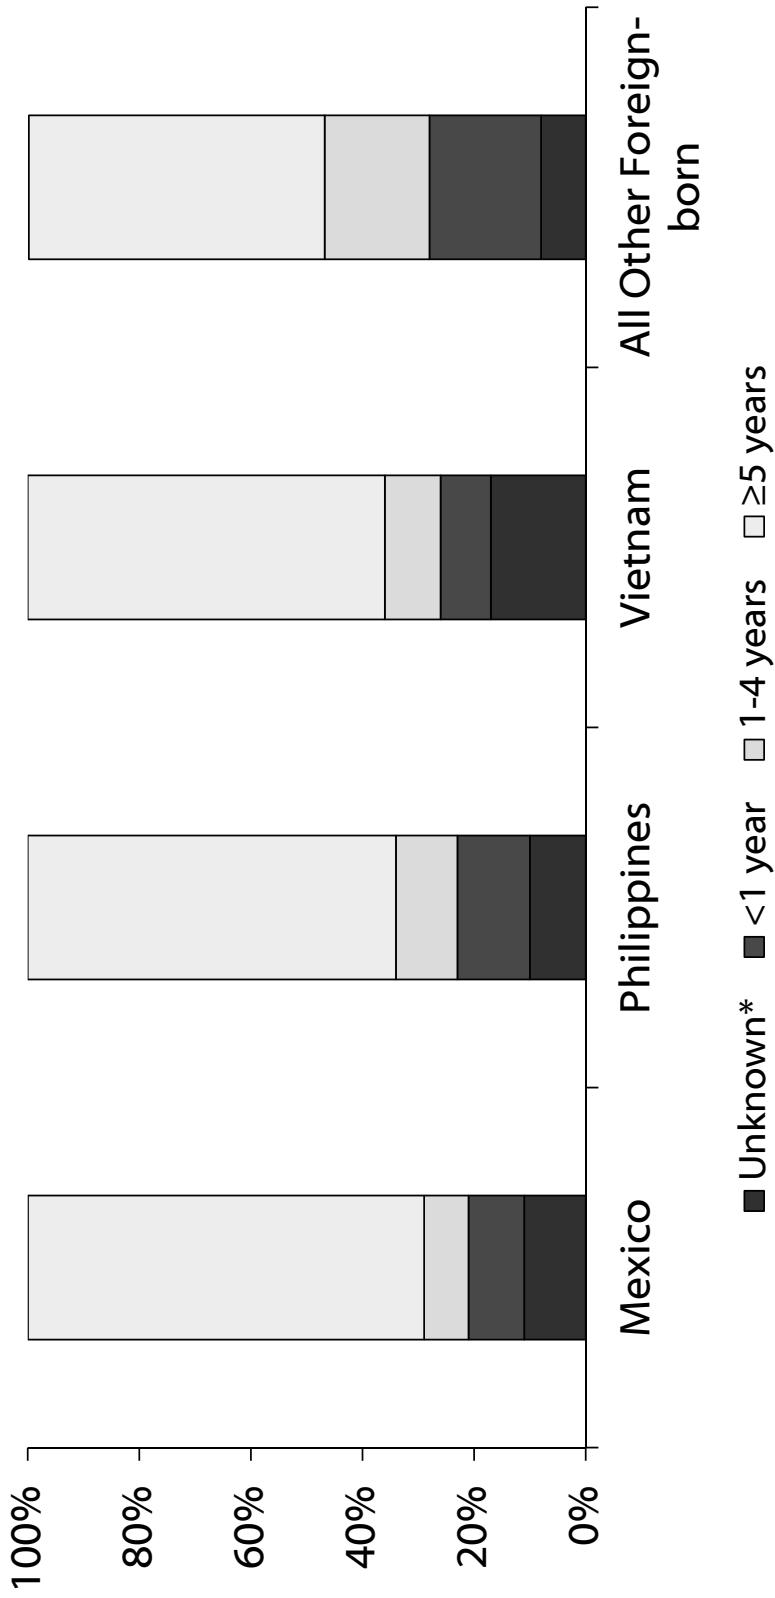

*Includes the same data as slide 17, but rates presented on a logarithmic scale.

**Updated as of June 5, 2015.

Countries of Birth of Foreign-born Persons Reported with TB, United States, 2014

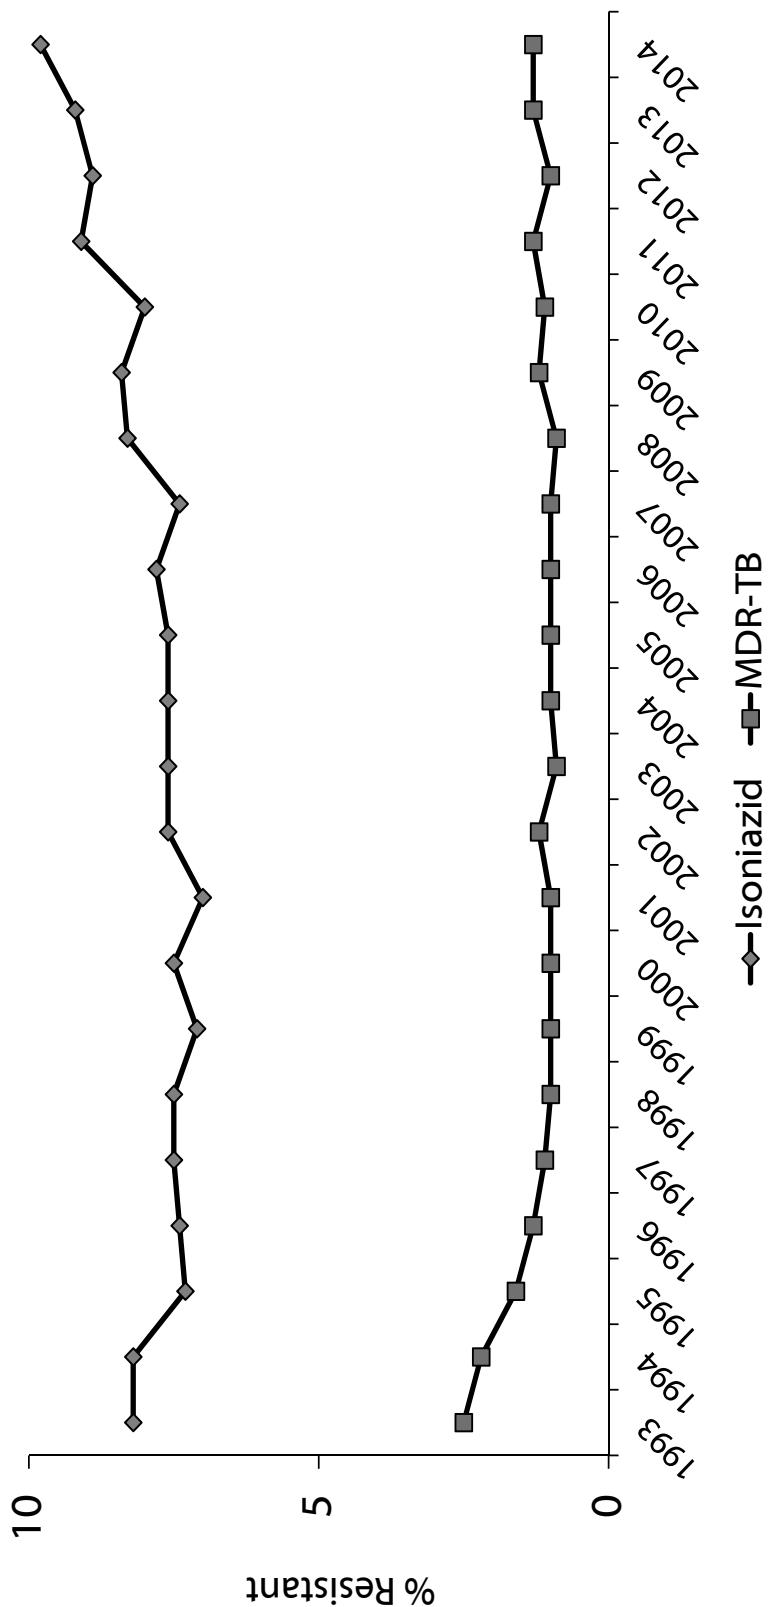

Percent of Foreign-born with TB by Time of Residence in U.S. Prior to Diagnosis, 2014

*Foreign-born TB patients for whom information on length of residence in the U.S. prior to diagnosis is unknown or missing.

Primary Anti-TB Drug Resistance, United States, 1993 - 2014*

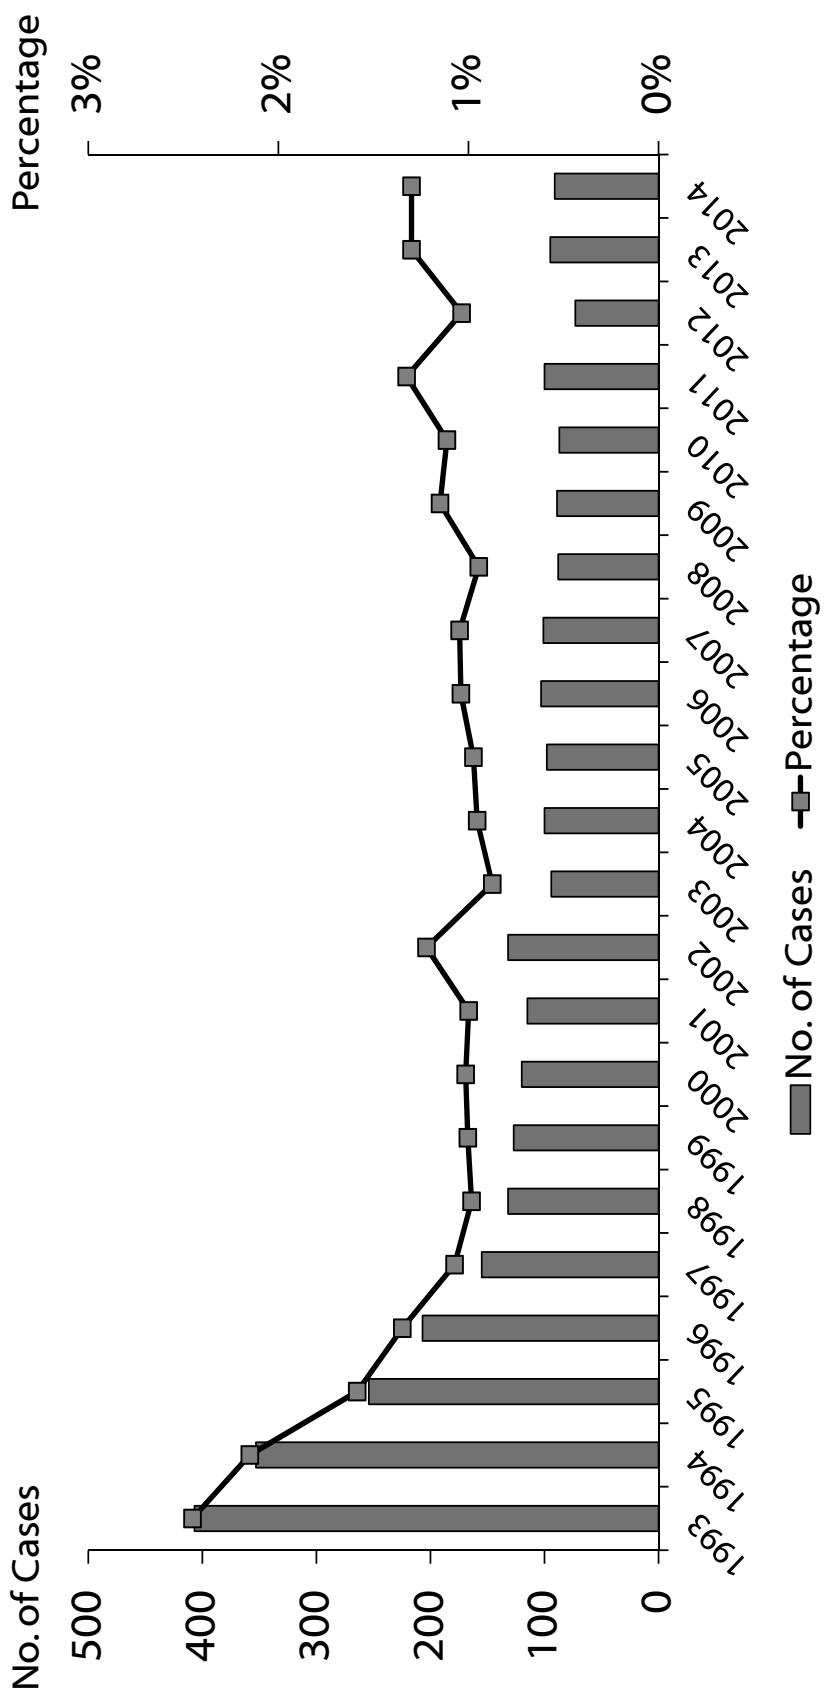

*Updated as of June 5, 2015.

Note: Based on initial isolates from persons with no prior history of TB. Multidrug resistant TB (MDR TB) is defined as resistance to at least isoniazid and rifampin.

Surveillance Slide #22

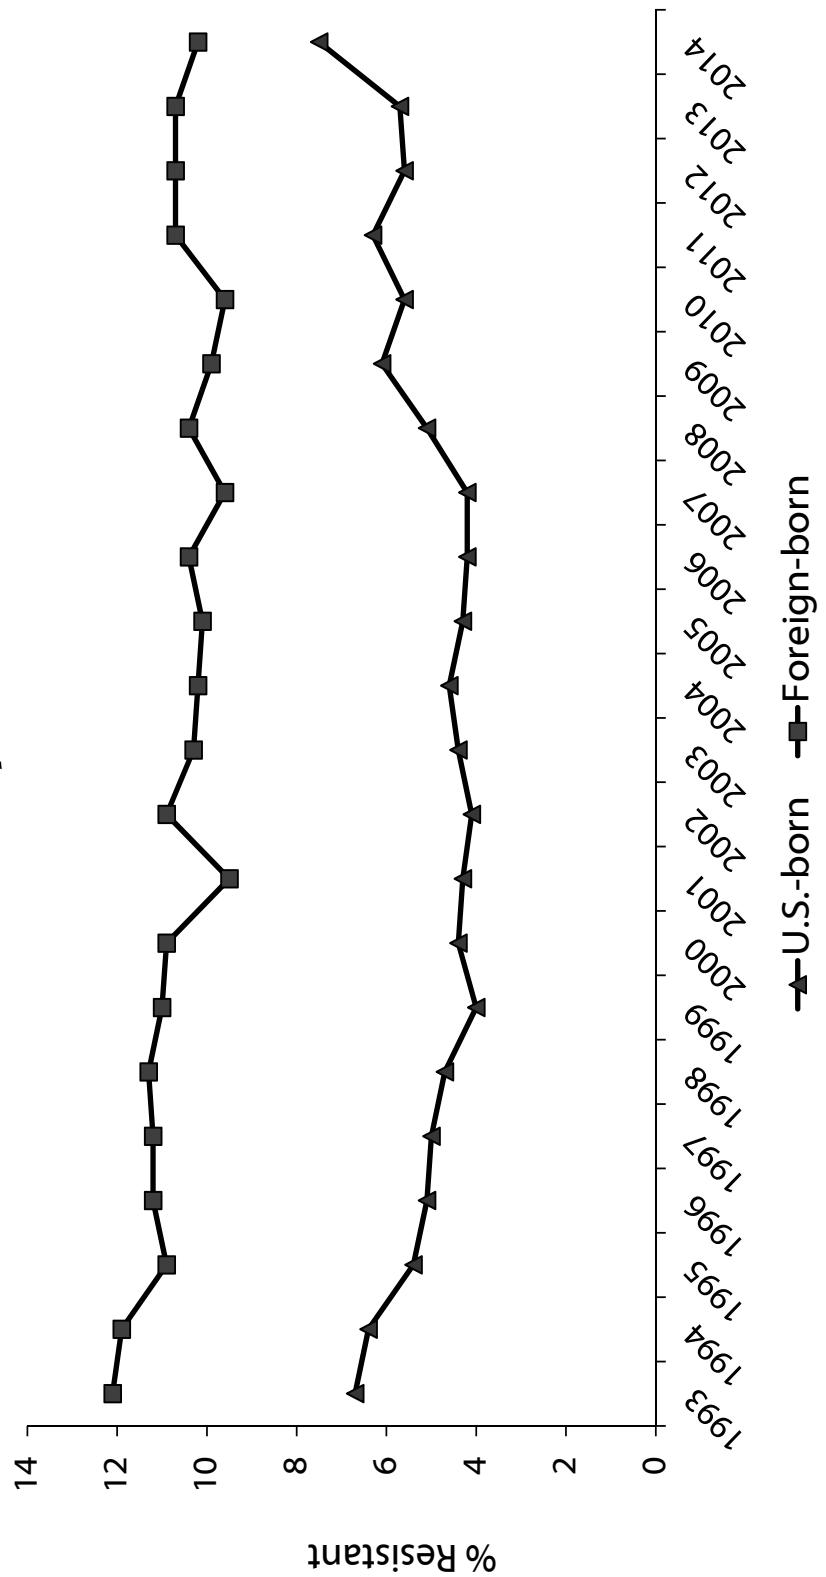

Primary MDR TB, United States, 1993 – 2014*

*Updated as of June 5, 2015.

Note: Based on initial isolates from persons with no prior history of TB. MDR TB defined as resistance to at least isoniazid and rifampin.

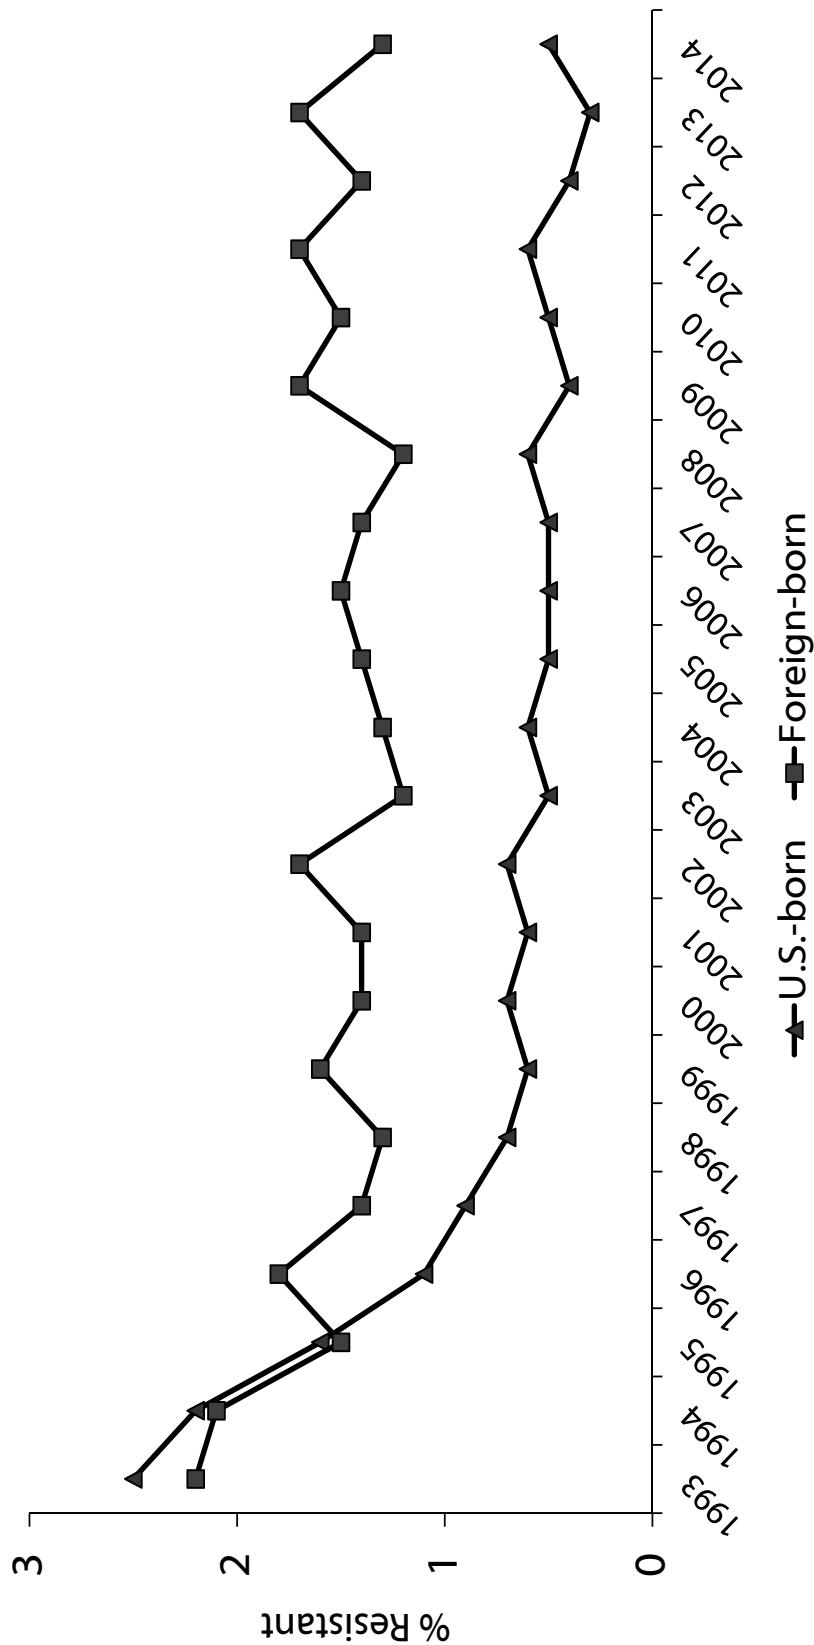

Primary Isoniazid Resistance in U.S.-born vs. Foreign-born Persons, United States, 1993 - 2014*

*Updated as of June 5, 2015.

Note: Based on initial isolates from persons with no prior history of TB.

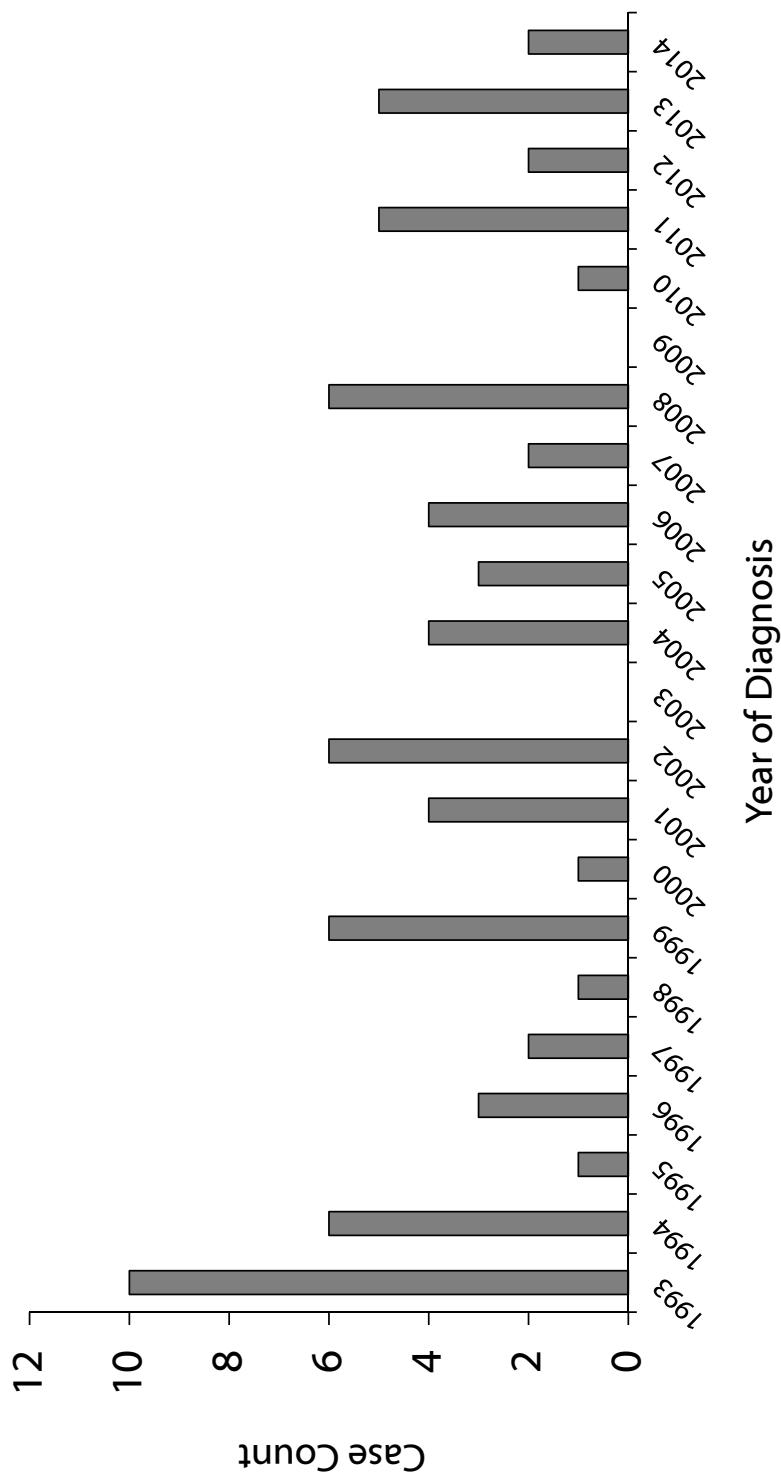

Primary MDR TB in U.S.-born vs. Foreign-born Persons United States, 1993 – 2014*

*Updated as of June 5, 2015.

Note: Based on initial isolates from persons with no prior history of TB. MDR TB defined as resistance to at least isoniazid and rifampin.

XDR TB Case Count Defined on Initial DST* by Year, 1993 – 2014**

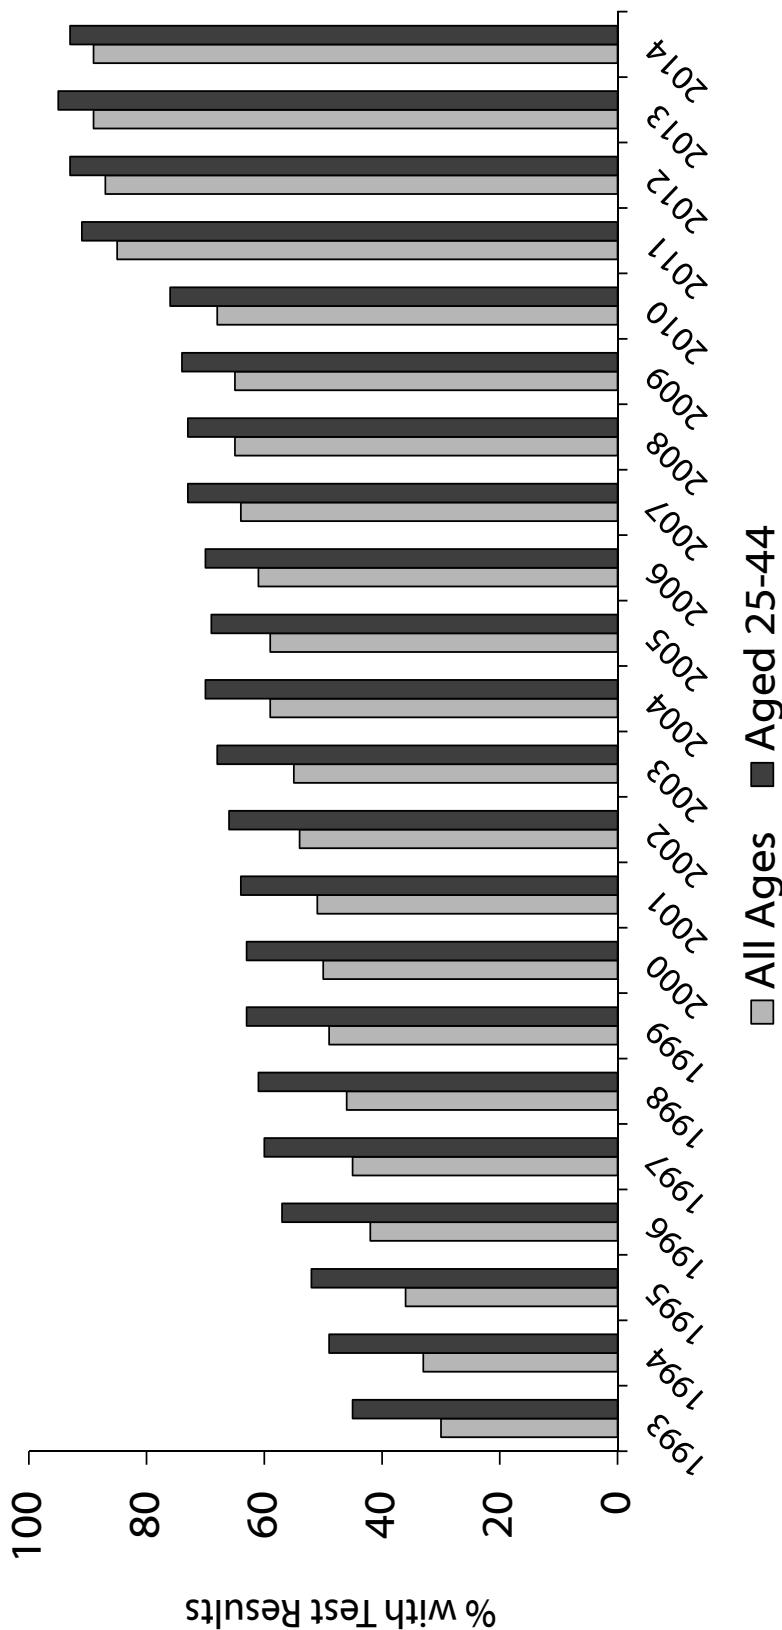

* Drug susceptibility test.

** Updated as of June 5, 2015.

Note: Extensively drug-resistant TB (XDR TB) is defined as resistance to isoniazid and rifampin, plus resistance to any fluoroquinolone and at least one of three injectable second-line anti-TB drugs.

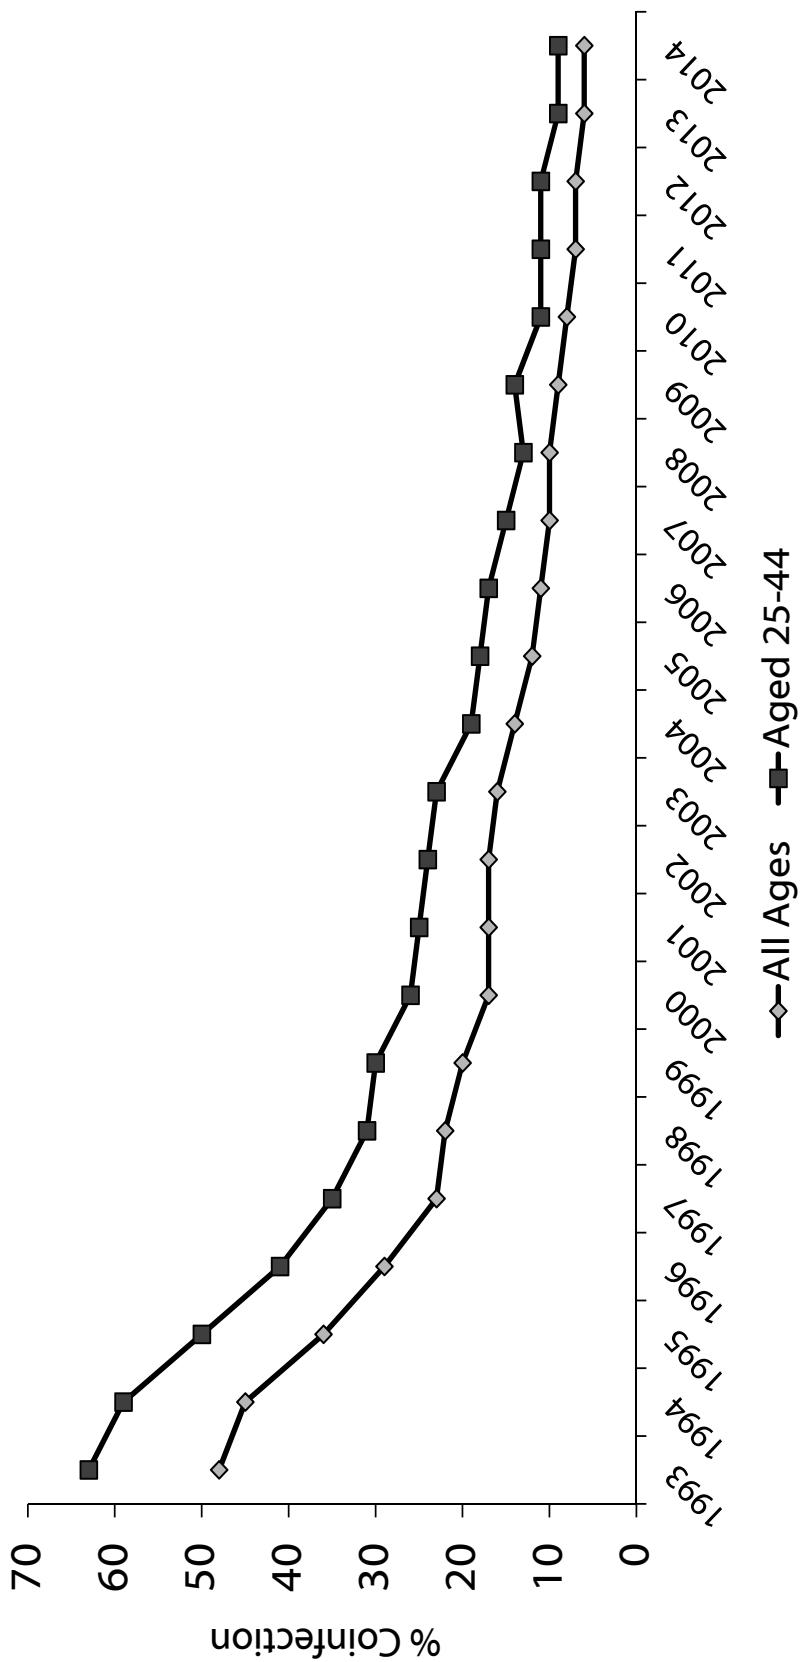

Reporting of HIV Test Results in Persons with TB by Age Group, United States, 1993 – 2014*

*Updated as of June 5, 2015.

Note: Includes persons with positive, negative, or indeterminate HIV test results and persons from California with co-diagnosis of TB and AIDS. Rhode Island did not report HIV test results for years 1993–1997. HIV test results for Vermont are not included for years 2007–2010. HIV test results for California are not included for years 2005 – 2010.

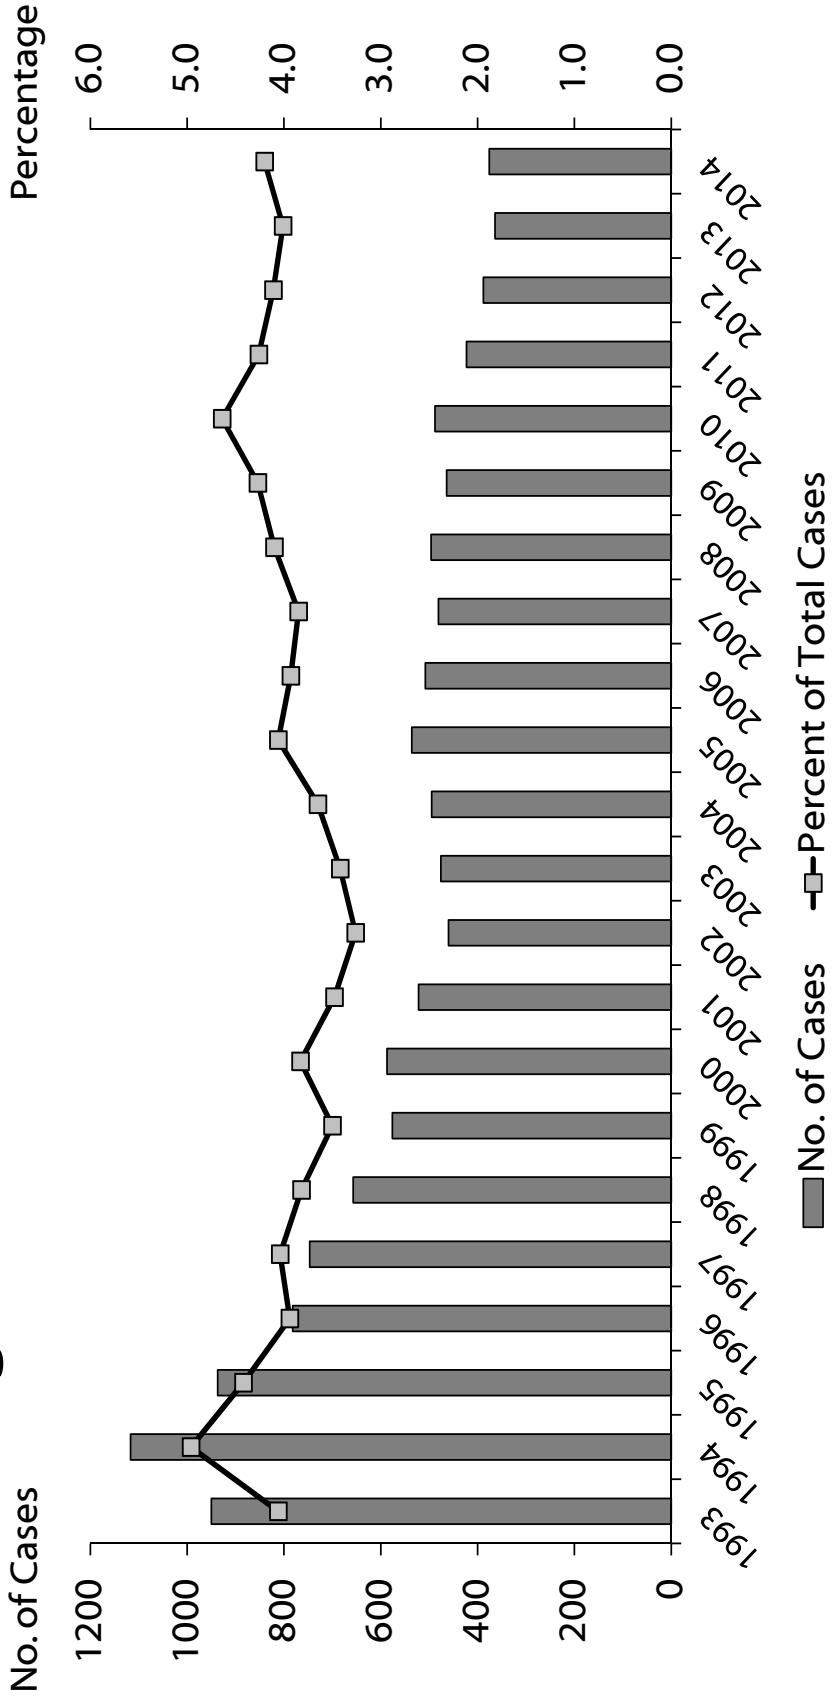

Estimated HIV Coinfection in Persons Reported with TB, United States, 1993 – 2014*

*Updated as of June 5, 2015.

Note: Minimum estimates based on reported HIV-positive status among all TB cases in the age group.

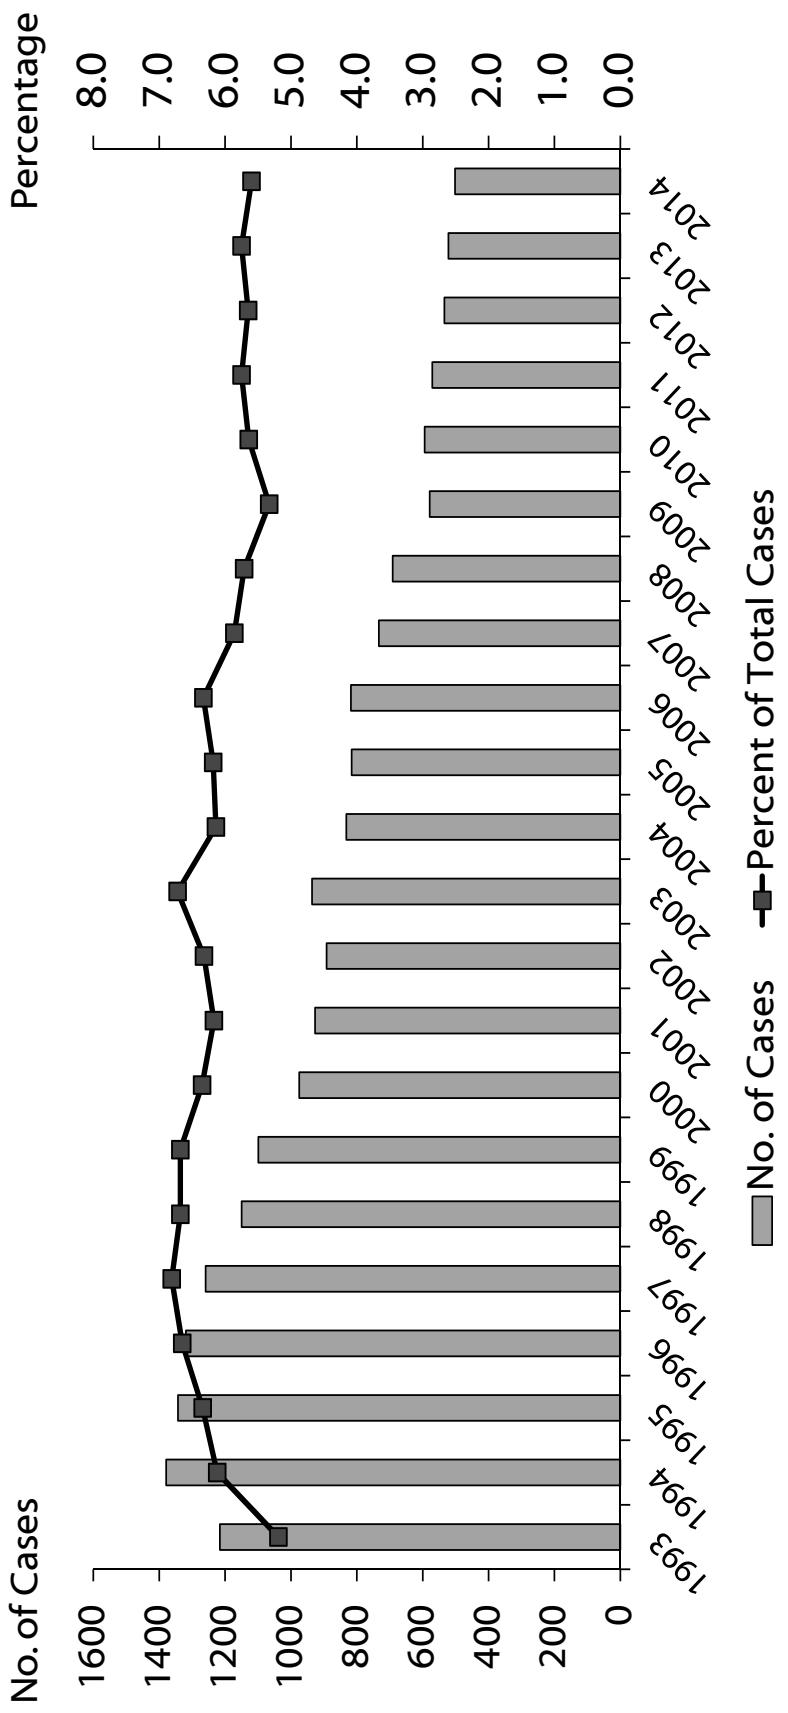

TB Cases by Residence in Correctional Facilities, Age ≥ 15 , United States, 1993-2014*

*Updated as of June 5, 2015.

Note: Resident of correctional facility at time of TB diagnosis.

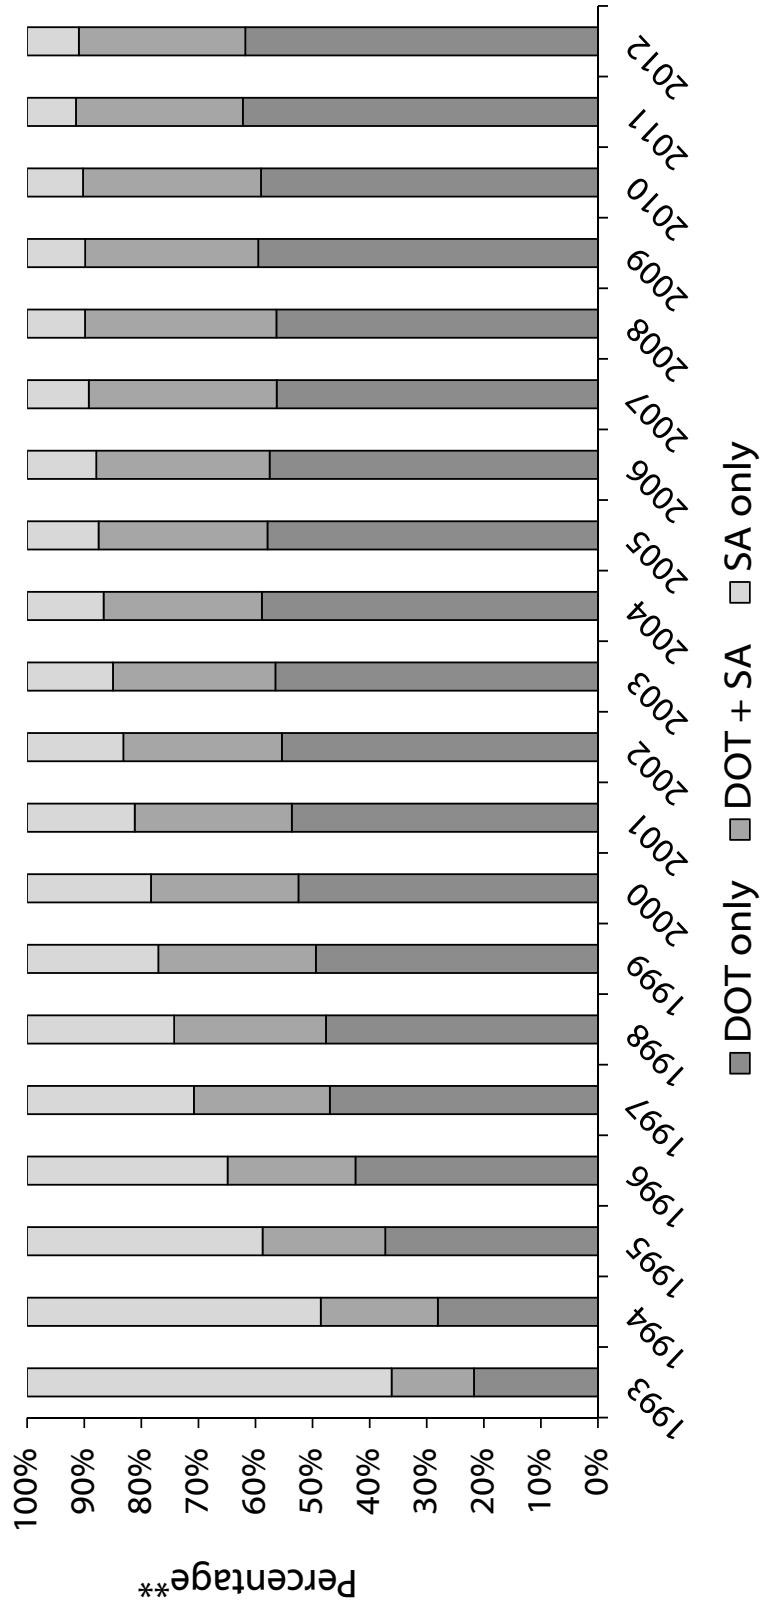

TB Cases Reported as Homeless in the 12 Months Prior to Diagnosis, Age ≥ 15 , United States, 1993-2014*

*Updated as of June 5, 2015.

Note: Homeless within past 12 months of TB diagnosis.

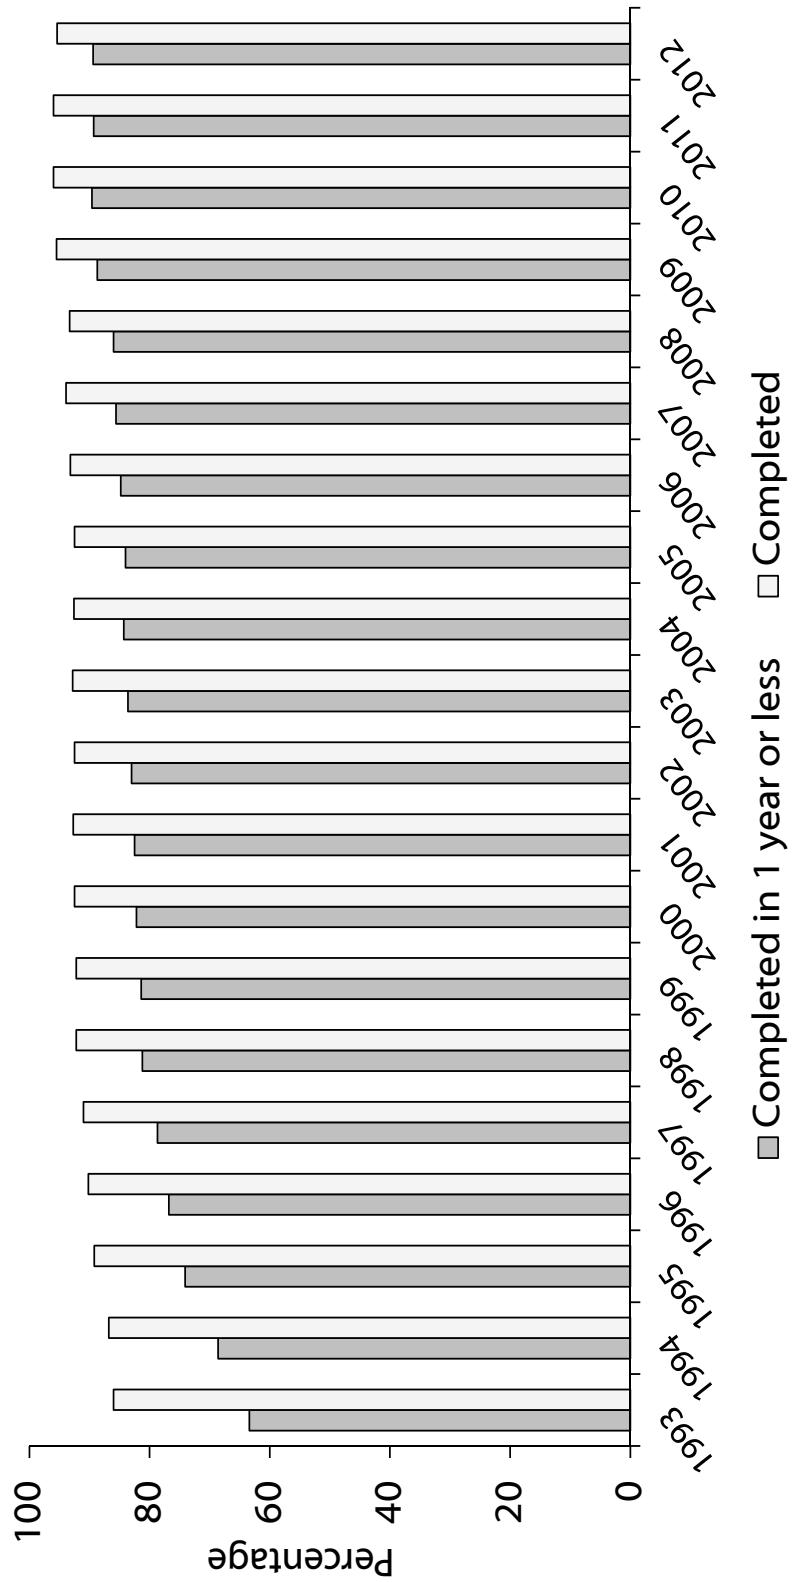

Mode of Treatment Administration in Persons Reported with TB, United States, 1993 - 2012*

*Updated as of June 5, 2015. Data available through 2012 only.

**Percentage of total cases in persons alive at diagnosis, with an initial regimen of one or more drugs prescribed, and excluding cases with unknown mode of treatment administration.
Directly observed therapy (DOT); Self-administered therapy (SA).

Completion of TB Therapy, United States, 1993 - 2012*

* Updated as of June 5, 2015. Data available through 2012 only.

Note: Includes persons alive at diagnosis, with initial drug regimen of one or more drugs prescribed, who did not die during therapy. Excludes persons with initial isolate rifampin resistant, or patient with meningeval disease, or pediatric patient (aged <15) with miliary disease or positive blood culture.

Definition for Tuberculosis Genotyping in the United States

Spoligotype:
000000000003771

Initial 12-locus MIRU-VNTR¹:
223325173533

Sequentially assigned for
each unique spoligotype
and initial 12-locus MIRU-
VNTR combination

PCRTypE:
PCR00002

Additional 12-locus
MIRU-VNTR (MIRU2):
444534423428²

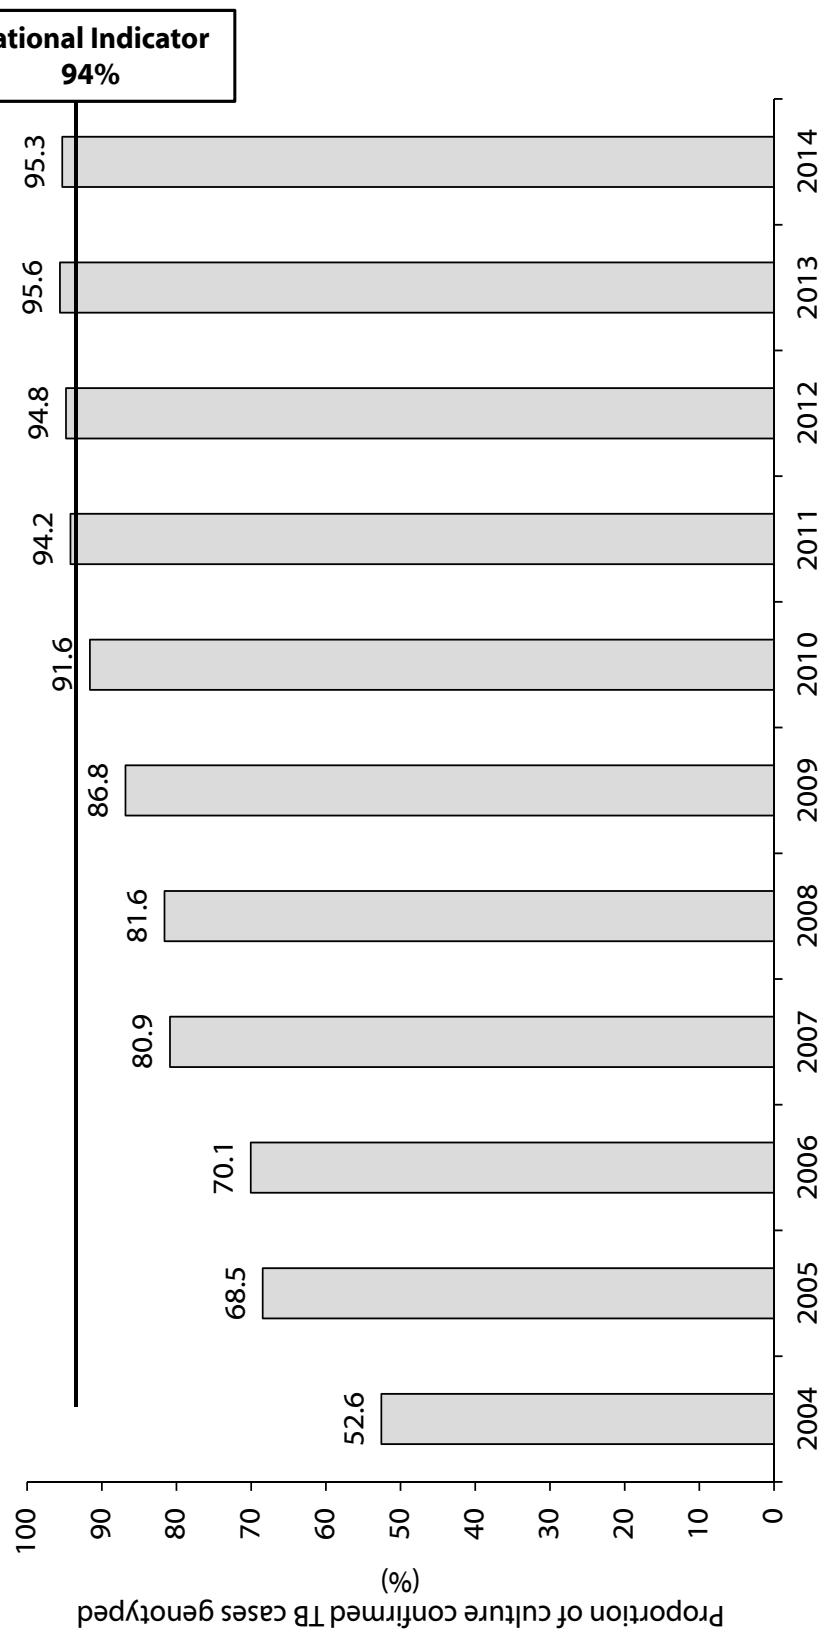

Sequentially assigned for each
unique spoligotype and 24-
locus MIRU-VNTR combination

GENTypE:
G00010

¹ Mycobacterial interspersed repetitive unit-variable number tandem repeat.

² The complete set of 24 loci is referred to as 24-locus MIRU-VNTR and is used for GENTypE designation for genotype in the United States.

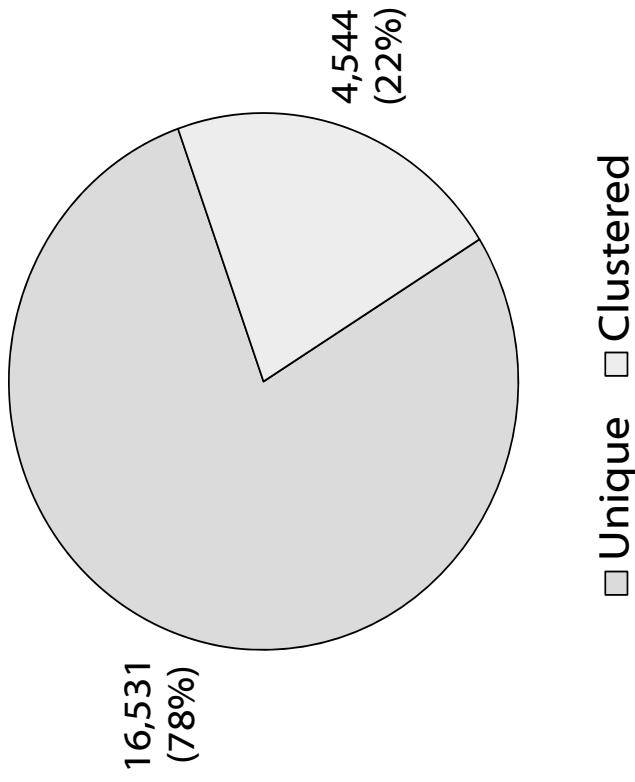

National Tuberculosis Genotyping Surveillance Coverage* by Year: United States**, 2004–2014

* The proportion of positive cultures with at least one genotyped isolate.

** Includes 50 states and the District of Columbia.

Number and Percent of Unique* and County-GENType Clustered** Cases, United States, 2012–2014

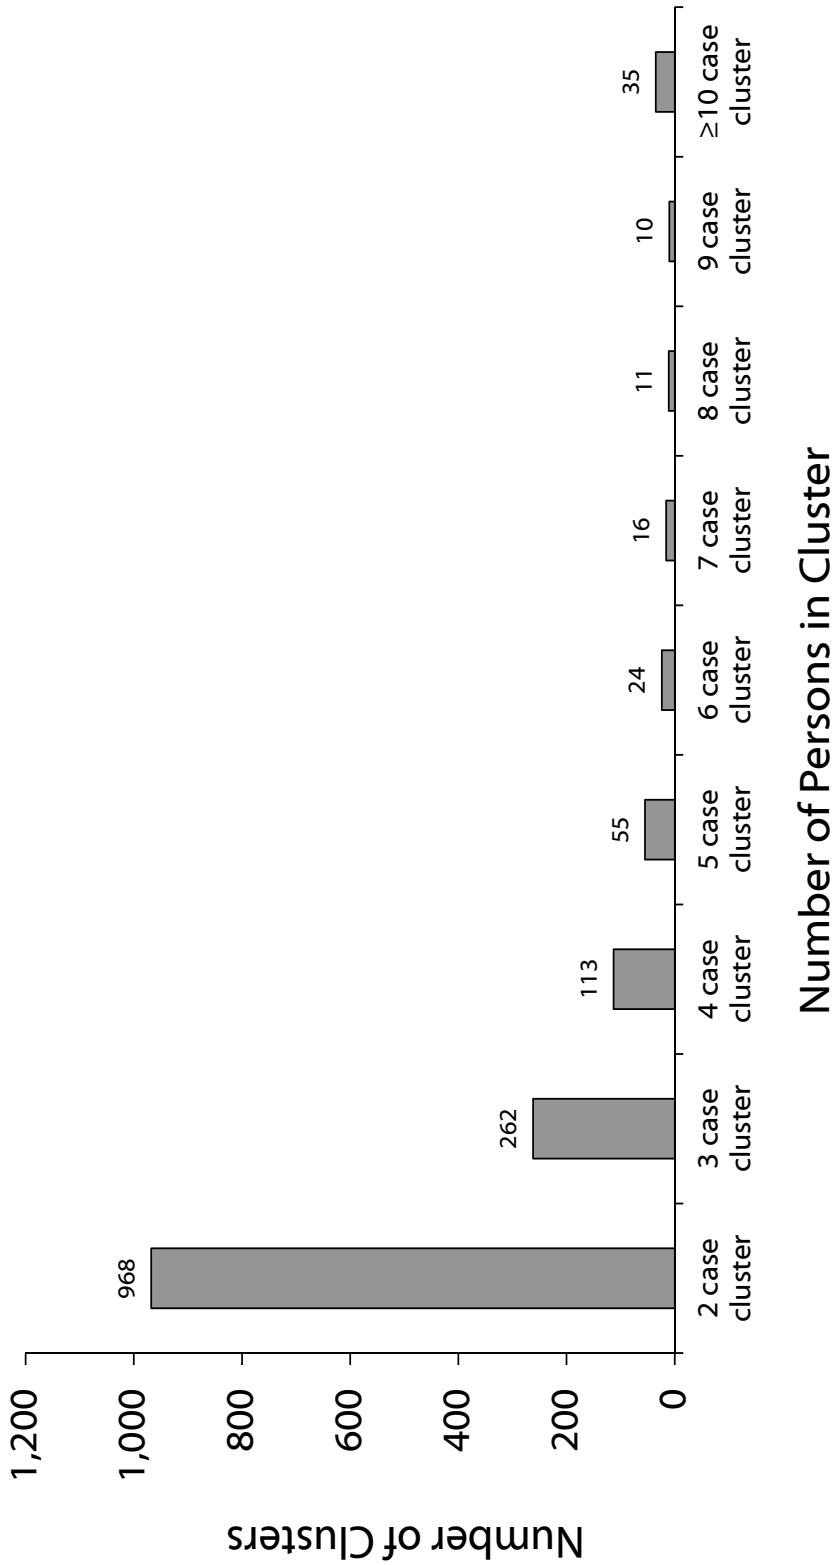

*Unique case is a case with a spoligotype and 24-locus MIRU-VNTR (GENType) that does not match any other case in that county during the specified 3-year time period.

** Two or more cases with matching spoligotype and 24-locus MIRU-VNTR (GENType) within a county during the specified 3-year time period.

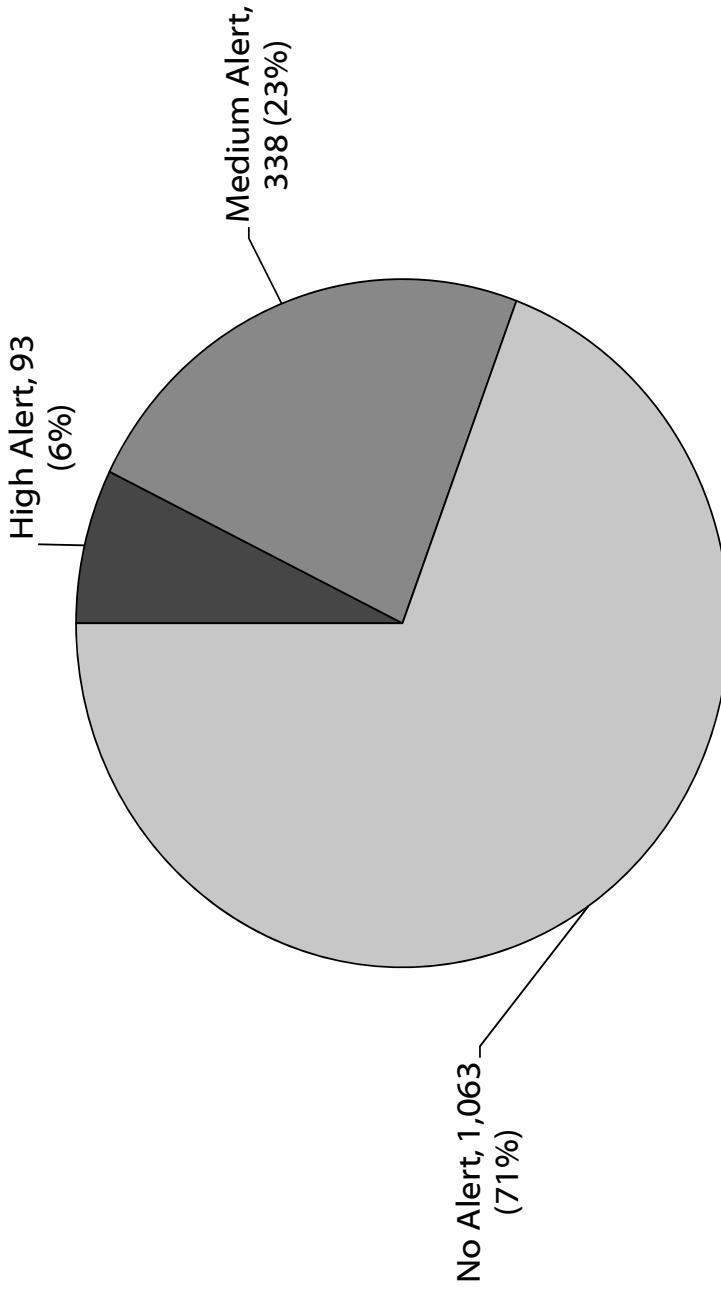

Surveillance Slide #35

Number of County-based Tuberculosis Genotype Clusters* by Cluster Size, United States, 2012-2014

* Genotype cluster is defined as two or more cases with matching spoligotype and 24-locus MIRU-VNTR (GENType) within a county during the specified 3-year time period.

Tuberculosis Genotype Clusters by TB GIMS* Alert Levels**, United States, 2012-2014

*Tuberculosis Genotyping Information Management System

**Alert level is determined by the log likelihood ratio statistic (LLR) for a given cluster, identifying higher than expected geospatial concentrations for a TB genotype cluster in a specific county, compared to the national distribution of that genotype; TB GIMS generates alert level notifications based on this statistic: "No alert" is indicated if LLR is between 0-5, "medium" is for LLR of 5.1-10 and "high" alert is for clusters with LLR > 10.

Tuberculosis in the United States

National Tuberculosis Surveillance System Highlights from 2014

Slide 1 (title slide). Tuberculosis in the United States—National Tuberculosis Surveillance System, Highlights from 2014. This slide set was prepared by the Division of Tuberculosis Elimination, Centers for Disease Control and Prevention (CDC), Department of Health and Human Services (DHHS). It provides trends for the recent past and highlights data collected through the National Tuberculosis Surveillance System for 2014. Since 1953, through the cooperation of state and local health departments, CDC has collected information on newly reported cases of tuberculosis (TB) disease in the United States. The data presented here were collected via the revised TB case report introduced in 2009. Currently, each individual TB case report (Report of Verified Case of Tuberculosis or RVCT) is submitted electronically to CDC. The data for this slide set are based on updates received by CDC as of June 5, 2015. All case counts and rates for years 1993–2014 have been updated.

Slide 2. Reported TB Cases, United States, 1982–2014. The resurgence of TB in the mid-1980s was marked by several years of increasing case counts until its peak in 1992. Case counts began decreasing again in 1993, and 2014 marked the twenty-second year of decline in the total number of TB cases reported in the United States since the peak of the resurgence. From 1992 until 2002, the total number of TB cases decreased 5%–7% annually. From 2002 to 2003, however, the total number of TB cases decreased by only 1.4%. An unprecedented decrease occurred in 2009, when the total number of TB cases decreased by more than 10% from 2008 to 2009. In 2014, a total of 9,421 cases were reported from the 50 states and the District of Columbia (DC). This represents a decline of 1.5% from 2013 and 64.7% from 1992.

Slide 3. TB Morbidity, United States, 2009–2014. This slide provides the total number of reported U.S. TB cases and the associated rates for each of the past 6 years. Rate is defined as cases per 100,000 population. The number of TB cases decreased from 11,523 in 2009 to 9,421 in 2014, and the TB rate decreased from 3.8 in 2009 to 3.0 in 2014.

Slide 4. TB Case Rates, United States, 2014. This map shows TB rates for 2014. Forty-one states reported a rate less than or equal to 3.0 TB cases per 100,000, the 2014 national average. Ten states and DC reported a rate above 3.0 TB cases per 100,000; these accounted for 57% of the national total in 2014 and have experienced substantial overall decreases in cases and rates from 1992 through 2014.

Slide 5. Map of U.S.-Affiliated Pacific Islands by TB Case Rates, 2014. This map of the Pacific region shows the case rates by jurisdiction.

Slide 6. TB Case Rates, U.S.-Affiliated Pacific Islands, 2014. This bar chart shows TB rates for the U.S. Pacific Islands for reported cases in 2014. These case rates range from 1.8 per 100,000 in American Samoa to 212.7 per 100,000 in the Republic of the Marshall Islands. The overall case rate for the United States (3.0 per 100,000) and for Hawaii (9.6 per 100,000) are also shown.

Slide 7. TB Case Rates by Age Group, United States, 1993–2014. This slide shows the last 22 years' declining trend in TB rates by age group. In 2014, case rates in all age groups declined by more than 50% from 1993 values: persons 65 years and older (from 17.7 per 100,000 in 1993 to 4.8 in 2014); adults aged 45 to 64 years (from 12.4 to 3.5); adults aged 25 to 44 years (from 11.5 to 3.4); those 15 to 24 years of age (from 5.0 to 2.2); and in children under 15 years of age (from 2.9 to 0.8).

Slide 8. Reported TB Cases by Age Group, United States, 2014. This pie chart shows the age distribution of persons reported with TB in 2014. Five percent were children under 15 years of age, 10% were age 15 to 24, 30% were age 25 to 44, 31% were age 45 to 64, and 24% were at least 65 years old.

Slide 9. TB Case Rates by Age Group and Sex, United States, 2014. This slide graphs the TB rates in 2014 by age group and sex. It shows that rates tended to increase with age, ranging from a low of less than 1 per 100,000 in children aged 5 to 14 to a high of 6.9 per 100,000 in men 65 years and older. As age increased, the case rate in men increased faster than women; the rates in men 45 years and older were approximately more than twice those in same-age women.

Slide 10. TB Case Rates by Race/Ethnicity, United States, 2003–2014. This slide shows the declining trend in TB rates by race/ethnicity during the last 12 years. Asians had the highest TB rates, which declined from 29.9 per 100,000 in 2003 to 17.8 in 2014, and had a percent decline over the time period of 40.5%. Rates also declined in the following racial/ethnic groups: among non-Hispanic blacks or African-Americans, from 11.7 in 2003 to 5.1 in 2014 (-56%); among Hispanics, from 10.3 to 5.0 (-51%); among American Indians and Alaska Natives, from 8.2 to 5.0 (-39%); and among non-Hispanic whites, from 1.4 to 0.6 (-57%). Rates increased among Native Hawaiian or Other Pacific Islanders, from 16.2 to 16.9 (+4.3%).

Several important factors likely contribute to the disproportionate burden of TB in minorities. In persons who were born in countries where TB is common, TB disease may result from infection acquired in the country of origin. Unequal distribution of TB risk factors, such as HIV infection, may also contribute to increased exposure to TB or to an increased risk of developing TB once infected with *M. tuberculosis*.

Slide 11. TB Case Rates by Age Group and Race/Ethnicity, United States, 2014. This slide presents TB rates in 2014 by age group and race/ethnicity. After infancy (age under 5), risk typically increased with age across all racial and ethnic groups; excepting the Native Hawaiian/Other Pacific Islander race/ethnicity group which does not display a pattern. Rates were consistently higher in minority racial and ethnic groups than in non-Hispanic whites. Rates were the highest in Asians and Native Hawaiians and Other Pacific Islanders, particularly in adult age groups.

Slide 12. Reported TB Cases by Race/Ethnicity, United States, 2014. In 2014, 85% of all reported TB cases occurred in racial and ethnic minorities (32% in Asians, 29% in Hispanics, 21% in non-Hispanic blacks or African-Americans, 1% in American Indians or Alaska Natives, and 1% in Native Hawaiians or Other Pacific Islanders), whereas 13% of cases occurred in non-Hispanic whites. Persons reporting two or more races, not including persons of Hispanic or Latino origin, accounted for 2% of all cases.

Slide 13. Number of TB Cases in U.S.-born vs. Foreign-born Persons, United States, 1993–2014. This graph plots the number of U.S.-born vs. foreign-born persons reported with TB each year, from 1993 through 2014. It illustrates the increase in the percentage of cases occurring in foreign-born persons during this period, from 29% in 1993 to 66% in 2014. Overall, the number of cases in foreign-born persons remained virtually level, with approximately 7,600–8,000 cases each year before 2009, until 2009 when the number dropped to 6,961. That decreasing trend continued until 2013 with the number of foreign-born cases dropping to 6,189. However in 2014 the number of foreign-born cases increased to 6,215. The number in U.S.-born persons decreased from more than 17,000 in 1993 to 3,188 in 2014.

Slide 14. Trends in TB Cases in Foreign-born Persons, United States, 1993–2014. This slide shows trends in the past 22 years of TB cases in foreign-born persons in the United States from 1993 through 2014. The percentage of TB cases accounted for by foreign-born persons increased from 29% in 1992 to 66% in 2014.

Slide 15. Reported TB Cases by Origin and Race/Ethnicity, United States, 2014. Among U.S.-born persons with TB in 2014, 37% were non-Hispanic black or African-American, 30% were non-Hispanic white, 21% were Hispanic or Latino, 4% were Asian, 4% were American Indian or Alaska Native, and 3% were Native Hawaiian or Other Pacific Islander. Persons reporting two or more races totaled less than 1% of US born cases and are not shown. Among the foreign-born, 46% were Asian, 34% were Hispanic or Latino, 13% were non-Hispanic black or African-American, 4% were non-Hispanic white, and 2% were persons reporting two or more races, not including persons of Hispanic or Latino origin. Cases among American Indians or Alaska Natives and among Native Hawaiians or Other Pacific Islanders constituted less than 1%, respectively, of the cases among the foreign-born and are not shown.

Slide 16. Percentage of TB Cases Among Foreign-born Persons, United States, 2004 and 2014. The percentage range of the total number of TB cases that occurred in foreign-born persons in each state is highlighted for 2004 and 2014 in these side-by-side maps. The number of states with less than 25% of their TB cases among the foreign-born decreased from 10 states in 2004 to 8 states in 2014. The number of states with at least 25-49% of cases among the foreign-born decreased from 18 states in 2004 to 6 states in 2014. However, the number of states that had 50% or more of their cases among the foreign-born increased from 24 states in 2004 to 37 states in 2014.

Slide 17. TB Case Rates in U.S.-born vs. Foreign-born Persons, United States, 1993–2014. TB rates in foreign-born persons remain higher than those in the U.S.-born population. From 1993 through 2014, the rates in U.S.-born persons decreased from 7.4 per 100,000 to 1.2, whereas the rates in foreign-born persons decreased from 34.0 per 100,000 to 15.4.

Slide 18. TB Case Rates in U.S.-born vs. Foreign-born Persons, United States, 1993–2014. This is the same as Slide 17, but the rates are presented on a logarithmic scale to better illustrate the trend in TB rates among the U.S.-born and foreign-born. The lines show a greater rate of decline among the U.S.-born compared with the foreign-born during this period.

Slide 19. Countries of Birth of Foreign-born Persons Reported with TB, United States, 2014. This slide shows the overall distribution of the countries of birth of foreign-born persons reported with TB in 2014, with the top seven highlighted. The list of countries has remained relatively constant since 1986, when information on country of birth was first reported by all areas submitting reports to CDC. In 2014 the seven top countries accounted for over 60% of all foreign-born cases, with Mexico accounting for 21%; the Philippines, 12%; India, 8%; Vietnam, 8%; China, 7%; Guatemala, 3%; and Haiti, 3%. Persons from more than 135 other countries each accounted for 2% or less of the total, but altogether accounted for 39% of foreign-born persons reported with TB.

Slide 20. Percent of Foreign-born with TB by Time of Residence in U.S. Prior to Diagnosis, 2014. The length of U.S. residence among foreign-born persons prior to their TB diagnosis in 2013 is shown in these stacked bars. Overall, 16% had been in the United States for less than 1 year, 15% between 1 and 4 years, and 60% for at least 5 years. The distribution is also shown for the top three countries of birth: Mexico, the Philippines, and Vietnam. Among persons born in Mexico, 10% had been in the United States for less than 1 year, 8% between 1 and 4 years, and 71% for at least 5 years. Among persons born in the Philippines, 13% had been in the United States for less than 1 year, 11% between 1 and 4 years, and 66% for at least 5 years. Among persons born in Vietnam, 9% had been in the United States for less than 1 year, 10% between 1 and 4 years, and 64% for at least 5 years. Values for unknown length of residence in U.S. for these top three countries ranged between 10 – 17% for 2014.

Slide 21. Primary Anti-TB Drug Resistance, United States, 1993–2014. Primary drug resistance is shown for the past 22 years. The graph starts in 1993, the year in which the individual TB case reports submitted to the national surveillance system began collecting information on initial susceptibility test results for patients with culture-positive TB. Data were available for more than 85% of culture-positive cases for each year. Primary resistance was calculated by using data from persons with no reported prior TB episode. Resistance to at least isoniazid was 8.2% in 1993; however by 2014, this had increased to 9.8%. Resistance to at least isoniazid and rifampin, known as multidrug-resistant TB (MDR TB), was 2.5% in 1993. The percent of primary MDR TB has remained approximately stable since it decreased to 1.0% in 1998. In 2014 the percent of primary MDR TB was 1.3%.

Slide 22. Primary MDR TB, United States, 1993–2014. This graph focuses on trends in primary MDR TB (based on initial isolates from persons with no prior history of TB) in the United States from 1993 through 2014. The number of primary MDR TB cases, represented by bars, steadily declined from 407 in 1993 to 132 in 2002. Since then, the total number of primary MDR TB cases has fluctuated between 87 to 103 cases, with 91 cases reported for 2014. Primary MDR TB, shown by the line, decreased from 2.5% in 1993 to approximately 1.0% in 1998, and has fluctuated around 1.0% since then. In 2014, the percentage was 1.3%.

Slide 23. Primary Isoniazid Resistance in U.S.-born vs. Foreign-born Persons, United States, 1993–2014. This graph shows primary isoniazid resistance in U.S.-born vs. foreign-born persons. Based on initial isolates from persons with no prior history of TB, the percentage of isoniazid resistance has remained higher among foreign-born persons than among U.S.-born persons for all years measured. In foreign-born persons, the percentage declined from 12.1% in 1993 to 10.2% in 2014. In U.S.-born persons, the percentage decreased from 6.7% in 1993 to 4.2% in 2007, but has increased since then to 7.5% in 2014.

Slide 24. Primary MDR TB in U.S.-born vs. Foreign-born Persons, United States, 1993–2014. This graph highlights primary MDR TB in U.S.-born versus foreign-born persons. The percentage with primary MDR TB has declined among both groups since 1993, although the decline in the U.S.-born has been greater. As a result, the proportion of primary MDR TB cases in the US that are attributed to foreign-born persons increased from ap-

proximately 25% in 1993 to 85% in 2014 (not shown on slide). Among the U.S.-born, the percentage with primary MDR TB has been less than 1% since 1997 and was 0.5% in 2014. The percentage among foreign-born persons has fluctuated year by year, although it has remained between 1.2 and 1.8% since 1995. In 2014, the percentage of primary MDR TB among foreign-born persons was 1.3%

Slide 25. Extensively Drug Resistant (XDR) TB, as Defined on Initial Drug Susceptibility Testing (DST), United States, 1993–2014. This graph shows the annual number of counted XDR TB cases as defined on initial DST from 1993–2014. XDR TB is defined as resistance to isoniazid and rifampin, plus resistance to any fluoroquinolone and at least one of three injectable second-line anti-TB drugs. Two cases of XDR TB were reported in 2014. The most reported in a single year was 10 in 1993, while there were no cases reported in 2003 and 2009. There is no apparent trend in the number of cases over time.

Slide 26. Reporting of HIV Test Results in Persons with TB by Age Group, United States, 1993–2014. This slide shows the completeness of reporting of HIV test results in persons with TB by age group from 1993 through 2014. The percentage of TB patients for whom test results were reported increased from 30% among all ages in 1993 to 89% in 2014. Among adults aged 25–44 years, the percentage increased from 45% in 1993 to 93% in 2014. California began reporting HIV test results to CDC in 2011; this accounts for the substantial percentage increase for that year.

Slide 27. Estimated HIV Coinfection in Persons Reported with TB, United States, 1993–2014. This slide provides minimum estimates of HIV coinfection among persons reported with TB from 1993 through 2014. Since the addition of the request for HIV status to the individual TB case report in 1993, incomplete reporting has provided a challenge to calculating reliable estimates, although reporting improved substantially beginning in 2011 (see previous Slide 26). Results from the cross-matching of TB and AIDS registries have been used to supplement reported HIV test results. For all ages, the estimated percentage of HIV coinfection in persons who reported HIV testing (positive, negative, or indeterminate test results) with TB decreased from 48% to 6% overall from 1993 – 2014, and from 63% to 9% among persons aged 25 to 44 years during this period.

Slide 28. TB Cases by Residence in Correctional Facilities, Age ≥15, United States, 1993–2014. This graph highlights the number of cases that were a resident of any type of correctional facility at the time of TB diagnosis. Cases must have been 15 years of age or greater. The number of cases residing in a correctional facility has decreased from a high of 1,117 cases in 1994 to 376 cases in 2014. Between the years 2000 and 2010, the number of cases residing in a correctional facility ranged between the high-400s and high-500s; 2011 was the first year to drop below this range to 422 cases. Of total cases, the percentage of cases residing in a correctional facility has ranged from 5.0% in 1994 to 3.3% in 2002. The 1990s saw a decreasing trend in percentage until 2002. Since 2002, there has been an increasing trend in percentage; in 2014 the percentage of total cases was 4.2%.

Slide 29. TB Cases by Homeless Status, Age ≥15, United States, 1993–2014. This graph highlights the status of cases that were homeless within twelve months prior of TB diagnosis from 1993 through 2014. Cases must have been 15 years of age or greater. The number of homeless cases has decreased from a high of 1,379 cases in 1994 to 502 in 2014. This category has seen an overall decrease in cases since 1994; increases were observed in the years 2003 (6.7%), 2006 (6.3%), and 2010 (5.6%); these have been exceptions with a small increase in cases. Of total cases, 6.1% were homeless in 1994 and percentages have ranged between 6.8% in 1997 and a low of 5.3% in 2009. It has since increased to 5.6% in 2014.

Slide 30. Mode of Treatment Administration in Persons Reported with TB, United States, 1993–2012. In 1993, the reporting areas began providing information about mode of treatment administration on the individual TB case report form. Treatment administered as only directly observed therapy (DOT) increased from 21.7% in 1993 to 62% in 2012, the latest year with available data. The proportion of patients who received at least some portion of their treatment as DOT (based on combining the percentage of patients who received only DOT and the percentage for whom some portion was self-administered) was 29% in 2012.

Slide 31. Completion of TB Therapy, United States, 1993–2012. The reporting areas began providing information on completion of therapy in 1993 through the individual TB case report form. The calculations exclude persons with initial isolate rifampin resistant, or patient with meningeal disease, or pediatric patients (aged <15) with miliary disease or a positive blood culture. Overall completion of therapy had remained at approximately 92-

93% from 1998 through 2008, but increased to 96% in 2010 and 2011. In 2012, the latest year with available data, completion of therapy was 95%. Completion in 1 year or less increased from 63% in 1993 to 89% in 2012. The current DHHS Healthy People 2020 objective is completion of therapy in 1 year or less in 93% of patients. CDC is working with state and local health departments to determine and evaluate reasons for apparently delayed completion of therapy, which may vary by jurisdiction.

Slide 32. Definition for Tuberculosis Genotyping in the United States. This slide shows the schematic for sequential assignment of unique spoligotypes and initial 12-locus MIRU-VNTR combination or 24-locus MIRU-VNTR combination.

Slide 33. National Tuberculosis Genotyping Surveillance Coverage by Year, United States, 2004–2014. This slide shows the increase in genotyping surveillance coverage from 2004 to 2014. In 2004 the proportion of positive cultures with at least one genotyped isolate was 52.6%; in 2014 it was 95.3%. The national indicator for genotyping surveillance coverage is 94%.

Slide 34. Number and Percent of Unique and County-GENType Clustered Cases, United States, 2012–2014. This slide shows a chart with the percentage of unique and clustered cases. Unique cases are those with a spoligotype and 24-locus locus MIRU-VNTR (GENType) that does not match any other case in that county during the specified three year time period. Clustered cases are two or more cases with matching spoligotype and 24-locus MIRU-VNTR (GENType) within a county during the specified three year time period. In the 2012 – 2014 three year time period, there were 78% unique cases, and 22% clustered cases.

Slide 35. Number of County-based Tuberculosis Genotype Clusters by Cluster Size, United States, 2012–2014. This slide shows the number of county-based TB genotype clusters by the size of the clusters; genotype cluster is defined as two or more cases with matching spoligotype and 24-locus MIRU-VNTR (GENType) within a county during the specified three year time period. In the 2012 – 2014 three year time period, there were 968 two-case clusters, 262 three-case clusters, 113 four-case clusters, 55 five-case clusters, 24 six-case clusters, 16 seven-case clusters, 11 eight-case clusters, 10 nine-case clusters, and 35 case clusters that were greater or equal to 10 in size.

Slide 36. Tuberculosis Genotype Clusters by TB GIMS Alert Levels, United States, 2012–2014. This slide shows a chart with percentage of genotype clusters by alert level. Alert level is determined by the log likelihood ratio statistic (LLR) for a given cluster, identifying higher than expected geospatial concentrations for a TB genotype cluster in a specific county, compared to the national distribution of that genotype; TB GIMS generates alert level notifications based on this statistic: “No alert” is indicated if LLR is between 0 – <5, “medium” is for LLR of 5 – <10 and “high” alert is for clusters with LLR ≥10. In the 2012-2014 three year time period, high alerts made up 6% of the total, medium alerts were 23%, and no alert were 71%.

Appendices

Appendix A

Tuberculosis Case Definition for Public Health Surveillance (Revised May 13, 2009)

Clinical description

A chronic bacterial infection caused by *Mycobacterium tuberculosis*, usually characterized pathologically by the formation of granulomas. The most common site of infection is the lung, but other organs may be involved.

Clinical case definition

A case that meets **all** of the following criteria:

- A positive tuberculin skin test result or positive interferon gamma release assay for *M. tuberculosis*
- Other signs and symptoms compatible with tuberculosis (TB) (e.g., abnormal chest radiograph, abnormal chest computerized tomography scan or other chest imaging study, or clinical evidence of current disease)
- Treatment with two or more anti-TB medications
- A completed diagnostic evaluation

Laboratory criteria for diagnosis

- Isolation of *M. tuberculosis* complex from a clinical specimen,*
or
- Demonstration of *M. tuberculosis* complex from a clinical specimen by nucleic acid amplification test,†
or
- Demonstration of acid-fast bacilli in a clinical specimen when a culture has not been or cannot be obtained or is falsely negative or contaminated.

Case classification

Confirmed: a case that meets the clinical case definition or is laboratory confirmed

Comment

A case should not be counted twice within any consecutive 12-month period. However, a case occurring in a patient who had previously had verified TB disease should be reported and counted again if more than 12 months have elapsed since the patient completed therapy. A case should also be reported and counted again if the patient was lost to supervision for greater than 12 months and TB disease can be verified again. Mycobacterial diseases other than those caused by *M. tuberculosis* complex should not be counted in tuberculosis morbidity statistics unless there is concurrent tuberculosis.

*Use of rapid identification techniques for *M. tuberculosis* (e.g., DNA probes and mycolic acid high-pressure liquid chromatography performed on a culture from a clinical specimen) are acceptable under this criterion.

†Nucleic acid amplification (NAA) tests must be accompanied by culture for mycobacteria species for clinical purposes. A culture isolate of *M. tuberculosis* complex is required for complete drug susceptibility testing and also genotyping. However, for surveillance purposes, CDC will accept results obtained from NAA tests approved by the Food and Drug Administration (FDA) and used according to the approved product labeling on the package insert, or a test produced and validated in accordance with applicable FDA and Clinical Laboratory Improvement Amendments (CLIA) regulations.

Appendix B

Recommendations for Reporting and Counting Tuberculosis Cases (Revised May 13, 2009)

Since publication of the “Recommendations for Counting Reported Tuberculosis Cases”¹ in July 1997, numerous changes have occurred, and many issues have been raised within the field of tuberculosis (TB) surveillance. This current version updates and supersedes the previous version.

A distinction should be made between *reporting* TB cases to a health department and *counting* TB cases for determining incidence of disease. Throughout each year, TB cases and suspected cases are reported to public health authorities by sources such as clinics, hospitals, laboratories, and health care providers. From these reports, the state or local TB control officer must determine which cases meet the current surveillance definition for TB disease and whether the case is countable. These countable TB cases are then reported to the Centers for Disease Control and Prevention (CDC).

Beginning in 2009, state and local TB control officers may also report to CDC those TB cases that are verified but not countable for morbidity statistics, as a measure of programmatic and case management burden. The noncountable report can include persons with TB disease recurring within a consecutive 12-month period after the patient completed TB therapy.

I. Reporting TB Cases. CDC recommends that health care providers and laboratories be required to report all TB cases or suspected cases to state and local health departments based on the current “Tuberculosis Case Definition for Public Health Surveillance” (Appendix A). This notification is essential in order for TB programs to:

- Ensure case supervision
- Ensure completion of appropriate therapy
- Ensure completion of contact investigations
- Evaluate program effectiveness
- Assess trends and characteristics of TB morbidity

II. TB Surveillance. For purposes of surveillance, a case of TB is defined on the basis of laboratory or clinical evidence of active disease due to *M. tuberculosis* complex.*

* Because most laboratories use tests that do not routinely distinguish *Mycobacterium tuberculosis* from very closely related species, these laboratories report culture results as being positive or negative for “*Mycobacterium tuberculosis* complex.” Although in almost all cases of human disease, isolates in the *M. tuberculosis* complex are, in fact, *M. tuberculosis*, other species are possible. Other species in the *Mycobacterium tuberculosis* complex include *M. bovis*, *M. africanum*, *M. microti*, *M. canetti*, *M. caprae*, *M. pinnipedii*, and *M. mungi*; the inclusion of these species in *M. tuberculosis* complex should not impact public health laboratories or programs, because only a few laboratories identify to the species level. These seven species are almost identical in DNA homology studies. In terms of their ability to cause clinical disease or be transmissible from person to person, *M. bovis*, *M. africanum*, *M. microti*, *M. canetti*, *M. pinnipedii*, and *M. mungi* behave like *M. tuberculosis*; therefore, disease caused by any of the organisms should be reported as TB, using the Report of Verified Case of Tuberculosis (RVCT). The only exception is the BCG strain of *M. bovis*, which may be isolated from persons who have received the vaccine for protection against TB or as cancer immunotherapy; disease caused by the BCG strain of *M. bovis* should not be reported as TB.

a. Laboratory Case Definition

- Isolation of *M. tuberculosis* complex from a clinical specimen. The use of rapid identification techniques for *M. tuberculosis* performed on a culture from a clinical specimen, such as DNA probes and high-pressure liquid chromatography (HPLC), is acceptable under this criterion.

OR

- Demonstration of *M. tuberculosis* from a clinical specimen by nucleic acid amplification (NAA) test. NAA tests must be accompanied by cultures of mycobacterial species. However, for surveillance purposes, CDC will accept results obtained from NAA tests approved by the Food and Drug Administration (FDA) and used according to the approved product labeling on the package insert, or a test produced and validated in accordance with applicable FDA and Clinical Laboratory Improvement Amendments (CLIA) regulations.

OR

- Demonstration of acid-fast bacilli (AFB) in a clinical specimen when a culture has not been or cannot be obtained or is falsely negative or contaminated; historically, this criterion has been most commonly used to diagnose TB in the postmortem setting.

b. Clinical Case Definition. In the absence of laboratory confirmation of *M. tuberculosis* complex after a diagnostic process has been completed, persons must have **all** of the following criteria for clinical TB:

- Evidence of TB infection based on a positive tuberculin skin test result or positive interferon gamma release assay for *M. tuberculosis*
- Current treatment with two or more anti-TB medications

AND

- One of the following:
 - (1) Signs and symptoms compatible with current TB disease, such as an abnormal chest radiograph or abnormal chest computerized tomography scan or other chest imaging study,

OR

- (2) Clinical evidence of current disease (e.g., fever, night sweats, cough, weight loss, hemoptysis)

NOTE: The software for TB surveillance developed by CDC includes a calculated variable called "Vercrit," for which one of the values is "Provider Diagnosis." "Provider Diagnosis" is selected when the user chooses to override a "Suspect" default value in the case verification screen as "Verified by Provider Diagnosis." Thus, "Provider Diagnosis" is not a component of the case definition for TB in the current "Tuberculosis Case Definition for Public Health Surveillance" (Appendix A). CDC's national morbidity reports have traditionally included all TB cases that are considered verified by the reporting areas, without a requirement that cases meet the published case definition.

- III. Counting TB Cases.** Cases that meet the current CDC surveillance case definition for verified TB are counted by 52 reporting areas with count authority (50 states, District of Columbia, and New York City) to determine annual incidence for the United States. The remaining 8 reporting areas (American Samoa, Federated States of Micronesia, Guam, Marshall Islands, Northern Mariana Islands, Puerto Rico, Republic of Palau, and U.S. Virgin Islands) report cases to CDC but are not included in the annual incidence for the United States. The laboratory and clinical case definitions are the two diagnostic categories used in the CDC “Tuberculosis Case Definition for Public Health Surveillance.”

Most verified TB cases are accepted for counting based on laboratory confirmation of *M. tuberculosis* complex from a clinical specimen.

A person may have more than one discrete (separate and distinct) episode of TB. If disease recurs in a person **within** any 12-consecutive-month period after the patient completed therapy, count only one episode as a case. However, if TB disease recurs in a person, **and** if more than 12 months have elapsed since the person completed TB therapy or was lost to supervision, the TB case is considered a separate episode and should be counted as a new case.

Mycobacterial diseases other than those caused by *M. tuberculosis* complex should not be counted in TB morbidity statistics unless there is concurrent TB.

a. Verified TB Cases

COUNT

Count only verified TB cases that meet the laboratory or clinical case definitions (see Section II). The diagnosis of TB must be verified by the TB control officer or designee. The current CDC surveillance case definition for TB describes and defines the criteria to be used in the case definition for TB disease.

DO NOT COUNT

If diagnostic procedures have not been completed, do not count; wait for confirmation of disease. Do not count as a case the patient for which two or more anti-TB medications have been prescribed for preventive therapy for exposure to multidrug-resistant (MDR) TB, or while the diagnosis is still pending.

b. Nontuberculous Mycobacterial Diseases (NTM)

COUNT

An episode of TB disease diagnosed concurrently with another nontuberculous mycobacterial disease should be counted as a TB case.

DO NOT COUNT

Disease attributed to or caused by nontuberculous mycobacteria alone should not be counted as a TB case.

c. TB Cases Reported at Death

COUNT

TB cases first reported to the health department at the time of a person's death are counted as incident cases, provided the person had current disease at the time of death. The TB control officer should verify the diagnosis of TB.

DO NOT COUNT

Do not count as a case of TB if there is no evidence of current disease at the time of death or at autopsy.

d. Immigrants, Refugees, Permanent Resident Aliens, Border Crossers,* and Foreign Visitors³

COUNT

Immigrants and refugees who are examined after arriving in the United States and diagnosed with clinically active TB requiring anti-TB medications should be reported and counted by the locality of their current residence at the time of diagnosis regardless of citizenship status.

Border crossers* who are diagnosed with TB and plan to receive anti-TB therapy from a locality in the United States for 90 days or more should be reported and counted by the locality where they receive anti-TB therapy.

Foreign visitors (e.g., students, commercial representatives, and diplomatic personnel) who are diagnosed with TB, are receiving anti-TB therapy, **and** have been, or plan to remain in, the United States for 90 days or more should be reported and counted by the locality of current residence.

DO NOT COUNT

Any person who was diagnosed and started on anti-TB drugs in another country should not be counted as a new case but should be reported as a verified noncountable TB case.

Border crossers* and foreign visitors who are diagnosed with TB and receive anti-TB therapy from a locality in the United States for less than 90 days but plan to return to their native country to continue therapy should not be reported or counted by the locality where they receive anti-TB therapy.

**Border crosser — defined, by the U.S. Citizenship and Immigration Services (US-CIS)² as “an alien resident of the United States reentering the country after an absence of less than six months in Canada or Mexico, or a nonresident alien entering the United States across the Canadian border for stays of no more than six months, or across the Mexican border for stays of no more than 72 hours.” Border crossers may go back and forth across the border many times in a short period*

e. Out-of-State or Out-of-Area Residents

COUNT

A person's TB case should be counted by the locality in which he or she resides at the time of diagnosis. TB in a person who has no address should be counted by the locality that diagnosed and is treating the TB. The TB control officer should notify the appropriate out-of-state or out-of-area TB control officer of the person's home locality to (1) determine whether the case has already been counted to avoid "double counting," and (2) agree on which TB control office should count the case if it has not yet been counted.

DO NOT COUNT

Do not count a case in a newly diagnosed TB patient who is an out-of-area resident and whose TB has already been counted by the out-of-area TB control office.

f. Migrants and Other Transients

COUNT

Persons without any fixed U.S. residence are considered to be the public health responsibility of their present locality and their TB case should be reported and counted where diagnosed.

DO NOT COUNT

Cases in transient TB patients should not be counted when there is evidence that they have already been counted by another locality.

g. Federal Facilities (e.g., Military and Veterans Administration Facilities)

COUNT

Cases in military personnel, dependents, or veterans should be reported and counted by the locality where the persons are residing in the United States at the time of diagnosis and initiation of treatment.

However, if military personnel or dependents are discovered to have TB at a military base outside the United States but are referred elsewhere for treatment (e.g., a military base located within the United States), the TB case should be reported and counted where treated and not where the diagnosis was made.

DO NOT COUNT

Do not count if the case was already counted by another locality in the United States.

h. Indian Health Service

COUNT

TB should be reported to the local health authority (e.g., state or county) and counted where diagnosed and treatment initiated. However, for a specific group such as

the Navajo Nation, which is geographically located in multiple states, health departments should discuss each case and determine which locality should count the case.

DO NOT COUNT

Do not count if the case was already counted by another locality.

i. Correctional Facilities (e.g., Local, State, Federal, and Military)

COUNT

Persons who reside in local, state, federal, or military correctional facilities may frequently be transferred or relocated within and/or between various correctional facilities. TB in these persons should be reported to the local health authority and counted by the locality where the diagnosis was made and treatment plans were initiated.

DO NOT COUNT

Do not count correctional facility residents' TB cases that were counted elsewhere by another locality or correctional facility, even if treatment continues at another locale or correctional facility.

j. Peace Corps, Missionaries, and Other Citizens Residing Outside the United States

DO NOT COUNT

TB in persons diagnosed outside the United States should not be counted. TB in these persons should be counted by the country in which they are residing, regardless of their plans to return to the United States for further work-up or treatment.

IV. Suggested Administrative Practices

To promote uniformity in TB case counting, the following administrative procedures are recommended:

- (a) All TB cases verified by the 52 reporting areas with count authority (50 states, District of Columbia, and New York City) during the calendar year (by December 31) will be included in the annual U.S. incidence count for that year. All tuberculosis cases verified during the calendar year by a reporting area with count authority from one of the remaining 8 reporting areas (American Samoa, Federated States of Micronesia, Guam, Marshall Islands, Northern Mariana Islands, Puerto Rico, Republic of Palau, and U.S. Virgin Islands) are also counted but are not included in the annual incidence for the United States. Cases for which bacteriologic results are pending or for which confirmation of disease is questionable for any other reason should not be counted until their status is clearly determined; they should be counted at the time they meet the criteria for counting. This means that a case reported in one calendar year could be included in the morbidity count for the following year. All reporting areas should ensure that there is agreement between final local and state TB figures reported to CDC. Currently, some reporting areas may not use this suggested protocol. Some of these areas may wait until the beginning of the following year when they have received and processed all of the TB cases for inclusion in the

annual case count for the previous year. If reporting areas decide to revise their protocols, they should be aware that their TB trends may change.

- (b) TB is occasionally reported to health departments over the telephone, by letter or fax, or on forms other than the Report of Verified Case of Tuberculosis (RVCT). Such information should be accepted as an official morbidity report if sufficient details are provided; otherwise, the notification should be used as an indicator of a possible TB case (suspect) which should be investigated promptly for confirmation.

V. TB Surveillance Definitions

Case - an episode of TB disease in a person meeting the laboratory or clinical criteria for TB as defined in the document “Tuberculosis Case Definition for Public Health Surveillance” (see Section II for criteria).

Suspect - a person for whom there is a high index of suspicion for active TB (e.g., a known contact to an active TB case or a person with signs or symptoms consistent with TB) who is currently under evaluation for TB disease.

Verification of a TB case - the process whereby a TB case, after the diagnostic evaluation is complete, is reviewed at the local level (e.g., state or county) by a TB control official who is familiar with TB surveillance definitions; if all the criteria for a TB case are met, the TB case is then verified and eligible for counting.

Counting of a TB case - the process whereby a reporting area with count authority evaluates verified TB cases against count criteria (e.g., assesses for case duplication). These cases are then counted for morbidity in that locality (e.g., state or county) and reported to CDC for national morbidity counting. Noncountable, verified cases may also be sent to CDC.

***Mycobacterium tuberculosis* complex** (*M. tuberculosis* complex) - Because most laboratories use tests that do not routinely distinguish *Mycobacterium tuberculosis* from very closely related species, these laboratories report culture results as being positive or negative for “*Mycobacterium tuberculosis* complex.” Although in almost all cases of human disease, isolates in the *M. tuberculosis* complex are, in fact, *M. tuberculosis*, other species are possible. For example, one study in San Diego found that 6% of human tuberculosis was caused by *Mycobacterium bovis*; cultures from these cases would be reported by most laboratories as being positive for *M. tuberculosis* complex. Other species in the *Mycobacterium tuberculosis* complex include *M. africanum*, *M. microti*, *M. canetti*, *M. caprae*, and *M. pinnipedii*. Although *M. microti*, *M. canetti*, *M. caprae*, and *M. pinnipedii* are newly described species, their inclusion in *M. tuberculosis* complex should not impact public health laboratories or programs because only a few laboratories identify to the species level. These seven species are almost identical in DNA homology studies. In terms of their ability to cause clinical disease or be transmissible from person to person, *M. bovis*, *M. africanum*, *M. microti*, *M. canetti*, *M. caprae*, and *M. pinnipedii* behave like *M. tuberculosis*; therefore, disease caused by any of the organisms should be reported as TB,

using the Report of Verified Case of Tuberculosis (RVCT). The only exception is the BCG strain of *M. bovis*, which may be isolated from persons who have received the vaccine for protection against TB or as cancer immunotherapy; disease caused by the BCG strain of *M. bovis* should not be reported as TB.

Nontuberculous mycobacteria (NTM) - mycobacteria other than *Mycobacterium tuberculosis* complex that can cause human infection or disease. Common nontuberculous mycobacteria include *M. avium* complex or MAC (*M. avium*, *M. intracelulare*), *M. kansasii*, *M. marinum*, *M. scrofulaceum*, *M. chelonae*, *M. fortuitum*, and *M. simiae*. Other terms have been used to represent NTM, including MOTT (mycobacteria other than TB) and “atypical” mycobacteria.

Reporting area - areas responsible for counting and reporting verified TB cases to CDC. Currently there are 60 reporting areas: the 50 states, District of Columbia, New York City, American Samoa, Federated States of Micronesia, Guam, Marshall Islands, Northern Mariana Islands, Puerto Rico, Republic of Palau, and U.S. Virgin Islands. The annual incidence of tuberculosis for the United States is based on 52 of these reporting areas (the 50 states, District of Columbia, and New York City).

Alien - defined by the U.S. Citizenship and Immigration Services (USCIS)² as “any person not a citizen or national of the United States.”

Border crosser - defined, by the U.S. Citizenship and Immigration Services (USCIS)² as “an alien resident of the United States reentering the country after an absence of less than six months in Canada or Mexico, or a nonresident alien entering the United States across the Canadian border for stays of no more than six months, or across the Mexican border for stays of no more than 72 hours.” Border crossers may go back and forth across the border many times in a short period.

Class A TB with waiver³

All applicants who have tuberculosis disease and have been granted a waiver.

Class B1 TB, Pulmonary³

No treatment

- Applicants who have medical history, physical exam, HIV, or CXR findings suggestive of pulmonary TB but have negative AFB sputum smears and cultures and are not diagnosed with TB or can wait to have TB treatment started after immigration.

Completed treatment

- Applicants who were diagnosed with pulmonary TB and successfully completed directly observed therapy prior to immigration. The cover sheet should indicate if the initial sputum smears and cultures were positive and if drug susceptibility testing results are available.

Class B1 TB, Extrapulmonary³

Applicants with evidence of extrapulmonary TB. Document the anatomic site of infection.

Class B2 TB, Latent TB Infection (LTBI) Evaluation³

Applicants who have a tuberculin skin test ≥ 10 mm but otherwise have a negative evaluation for TB. The size of the TST reaction, the applicant's status with respect to LTBI treatment, and the medication(s) used should be documented. For applicants who had more than one TST, whether the applicant converted the TST should be documented (i.e., initial TST < 10 mm but subsequent TST ≥ 10 mm).

Class B3 TB, Contact Evaluation³

Applicants who are a recent contact of a known tuberculosis case. The size of the applicant's TST reaction should be documented. Information about the source case, name, alien number, relationship to contact, and type of tuberculosis should also be documented.

Immigrant - defined by the USCIS² as “an alien admitted to the United States as a lawful permanent resident. Immigrants are those persons lawfully accorded the privilege of residing permanently in the United States. They may be issued immigrant visas by the Department of State overseas or adjusted to permanent resident status by the USCIS of the United States.”

Permanent Resident Alien - see Immigrant.

Waivers³ - A provision allows applicants undergoing pulmonary or laryngeal tuberculosis treatment to petition for a Class A TB with waiver. Waivers should be pursued for any immigrant or refugee who has a complicated clinical course and would benefit from receiving treatment of their tuberculosis in the United States. Applicants diagnosed with tuberculosis disease who are both smear- and culture-negative and will be traveling to the United States prior to start of treatment do not need to complete the waiver process.

Appendix C

National Surveillance for Severe Adverse Events Associated with Treatment for Latent Tuberculosis Infection - Reporting Information

This information is included to alert our public health partners of the importance of reporting severe (i.e., hospitalization or death) adverse events associated with treatment for latent TB infection (LTBI). Data on severe adverse events (SAEs) among persons receiving treatment for LTBI are needed to serve as a basis for periodic evaluation of guidelines for treatment of LTBI.

In April 2000, after the publication of updated *Guidelines for Targeted Tuberculin Testing and Treatment of Latent Tuberculosis Infection*¹, DTBE began receiving reports of SAEs related to the use of a 2-month course of rifampin and pyrazinamide (RZ) for treatment of LTBI. In response, DTBE requested and received reports and conducted on-site investigations of liver injury in persons on treatment for LTBI, and treatment guidelines were revised to recommend against the general use of rifampin and pyrazinamide to treat LTBI.^{2,3} In January 2004, DTBE implemented the National Surveillance System for Severe Adverse Events Associated with Treatment for LTBI, which collects reports about SAEs associated with any treatment regimen for LTBI, to quantify the frequency of SAEs and to characterize the clinical features of affected patients.⁴

Local medical providers should report possible LTBI-treatment associated SAEs to their respective local/state health departments. State health departments should report SAEs that occurred on or after January 1, 2004 to DTBE (e-mail: LTBIdruevents@cdc.gov).

Appendix D

Genotyping Background Information and Glossary

Tuberculosis (TB) genotyping is a laboratory-based analysis of the genetic material of the bacteria that cause TB disease, *Mycobacterium tuberculosis* complex. The total genetic content is referred to as the genome. Specific sections of the genome contain distinct genetic patterns that help distinguish different strains of *M. tuberculosis*. TB genotyping examines the location, number, and presence of different types of spacer or repetitive DNA patterns. The areas of the genome examined in TB genotyping are different from those related to drug resistance.

Applications of Genotyping

Persons with TB disease who are related by transmission should have matching genotype results. Conversely, persons with matching TB genotyping results are probably related by transmission in some way, although the connection might not be recent or direct.

Genotyping results, when combined with epidemiologic data, can help identify persons with TB disease involved in the same chain of transmission. This information adds value to conventional TB control activities in a variety of ways. These applications are summarized as follows:

Patient-level Applications of Genotyping

- Complete contact investigations
 - Confirm or refute patient connections (epidemiologic linkages) identified that may or may not be found through routine contact investigations
- Cluster investigations
 - Find patient connections that were not identified through routine contact investigations
- Detect, refute, or confirm potential false-positive culture results
- Distinguish relapse TB disease from new TB infection among TB cases with recurrent TB disease

Population-level Applications of Genotyping

- Detect potential outbreaks using geospatial or other analyses of genotype clusters
- Refute outbreaks when cases thought to be part of the same outbreak have non-matching genotype results
- Define the scope of potential outbreaks by identifying all cases in an area with a matching genotype
- Monitor known outbreaks over time by watching for new cases with the outbreak genotype that get added to existing clusters (outbreak surveillance)

History of TB Genotyping Surveillance in the United States

In 1996, CDC started the National Tuberculosis Genotyping Surveillance Network (NTGSN), a 5-year initiative which established the utility of genotyping in TB control efforts.¹

In 2004, based on the knowledge gained from NTGSN and associated studies,² CDC established the National TB Genotyping Service (NTGS) and funded a national genotyping laboratories, located in Michigan, to genotype at least one *M. tuberculosis* isolate from each culture-positive TB case reported in the United States.³ All TB control programs may use NTGS at no cost to the patients, healthcare providers, or health departments.

NTGS participation is voluntary, with individual programs determining how genotyping data will be used for their TB control activities. Since 2004, over 105,000 *M. tuberculosis* isolates have been successfully genotyped through NTGS and its partnerships between CDC, national genotyping laboratories, and 58 states and jurisdictions.

In 2010, CDC launched the TB Genotyping Information Management System (TB GIMS), a secure web-based database available to all 50 states, the District of Columbia, Puerto Rico, the U.S. Virgin Islands, and the U.S.-affiliated Pacific Islands. TB GIMS makes genotyping data easily available to users and links genotyping data to patient surveillance records. Key features include tools to link genotype results of isolate records from NTGS to patient surveillance records from the National TB Surveillance System (NTSS). Additional features include database queries on genotypes and clusters, data quality checks, aggregate reports, maps, and outbreak detection tools. TB GIMS currently has over 500 users among local, state, federal, and territorial partners.

Genotyping-based Outbreak Detection

CDC identifies genotype clusters that are most likely to represent TB outbreaks. Genotyping-based outbreak detection involves the use of geospatial analysis to identify unusual groupings of TB cases with matching genotypes that may represent outbreaks. TB control programs can use outbreak detection information to help allocate and prioritize resources for investigation and intervention on specific TB genotype clusters.

Currently, CDC's primary outbreak detection method is based on identifying higher than expected geospatial concentrations of a TB genotype in a specific county, compared to the national distribution of that genotype. This method calculates a log-likelihood ratio (LLR) statistic; clusters with higher LLRs are more likely to represent greater geospatial concentrations than clusters with lower LLRs; higher LLRs might indicate recent transmission of TB. LLR is then classified into alert levels within TB GIMS based on established cut points. Clusters are classified as no alert ($LLR < 5.0$), medium alert ($LLR \geq 5.0$ and < 10.0), or high alert (≥ 10.0). The alert level and changes in alert levels (e.g., from none to medium or high) can help TB programs identify outbreaks and prioritize TB genotype clusters for further investigation or intervention.

Genotyping Terminology

In NTGS, a genotype is currently defined as a unique combination of spacer oligonucleotide typing results (spoligotype) and 24-locus mycobacterial interspersed repetitive unit-variable number tandem repeat typing (MIRU–VNTR) results. Each unique combination of results is assigned a “GENType” designated as “G” followed by five digits, which are assigned sequentially to every genotype identified in the U.S. (e.g., G00162). This nomenclature is designed for convenience and ease of communication, but the specific numbers assigned have no additional significance outside of NTGS. Genotyping data from NTGS should not be used for clinical decision making.

National TB Genotyping Surveillance Coverage in the United States

National TB genotyping surveillance coverage refers to the proportion of culture-positive TB cases with a genotyped *M. tuberculosis* isolate. High levels of coverage in the United States can provide a better understanding of the epidemiology of TB transmission within a specific geographic area, as well as the entire country. Additionally, since outbreak detection algorithms are based on identifying unusual geospatial concentrations of genotypes, high coverage levels help decrease the likelihood of false-negative alerts. The National Tuberculosis Indicator Project (NTIP) national genotyping surveillance coverage objective is 94%.

GLOSSARY

Alert level

A mechanism used by TB GIMS to notify users of genotype clusters, possibly representing TB out-breaks, in a specific county. The alert level is determined by the log likelihood ratio statistic (LLR) for a given cluster. This is calculated by TB GIMS and is updated whenever a new case is added to a genotype cluster. Email notifications are generated whenever an alert level changes from a “none” LLR (0–5) to “medium” LLR (5.1–10) or “high” LLR (>10), or from a “medium” LLR to a “high” LLR.

Cluster investigation

A cluster investigation identifies epidemiologic links between TB patients whose isolates have matching genotypes. It may consist of reviewing information from public health and medical records and interviewing case managers and outreach workers. It can also involve re-interviewing TB patients.

Epidemiologic link (epi link)

An epidemiologic link is a relationship that two TB patients share that explains where, when, and how *M. tuberculosis* could have been transmitted between them. Patients that named each other as contacts have an epidemiologic link. However, an epidemiologic link could be a location where the two persons spent time together or an activity that brought them together.

Geospatial concentration

Geospatial concentration is a measure of how concentrated a genotype is in time and space. It suggests that recent transmission has occurred since cases with the same genotype in the same location are more likely to have come in contact with each other. TB GIMS uses the log likelihood ratio (LLR) to generate a numeric measure of geospatial concentration of a given TB genotype.

Genotype

The designation that represents one or more of the three genotyping techniques used for *M. tuberculosis*: spoligotyping, MIRU-VNTR analysis, and IS6110-based RFLP. These designations were developed to facilitate communication of genotyping information within and between TB programs. In the U.S., we use GENType or PCRTyp to define a genotype.

Genotyping cluster

A genotyping cluster consists of two or more cases in a jurisdiction during a specified time period with *M. tuberculosis* isolates that share matching genotypes. In the U.S., all cases with matching GENType or PCRTypre are considered to be in a genotype cluster. The jurisdiction and time period used vary based on the specific application of the term cluster. Within TB GIMS, a single county and a 3-year time period are used to define a cluster.

Genotype Surveillance Coverage

Genotyping surveillance coverage is defined as the proportion of culture-positive TB cases with a genotype result.

GENType

A designation for each unique combination of spoligotype and 24-locus MIRU–VNTR results. GENType is designated as “G” followed by five digits, which are assigned sequentially to every genotype identified in the U.S. (e.g., G00017).

LLR (log likelihood ratio)

A measure of the geographic concentration of a specific genotype in a county, compared to the national distribution of that same genotype, over a 3-year period. The higher the LLR, the greater the evidence that the local genotype cluster within the county represents a greater geospatial concentration than the national average, which might indicate recent transmission of *M. tuberculosis*.

Linking

In TB GIMS, linking refers to the process of connecting genotyping results with a reported TB case from the National TB Surveillance System (NTSS). This step is essential to ensure that demographic, risk factor and geographic data can be viewed in TB GIMS for genotype clusters.

MDR

Multidrug-resistant (MDR) tuberculosis strains are resistant to at least isoniazid (INH) and rifampin (RIF).

MIRU-VNTR

Mycobacterial interspersed repetitive unit–variable number tandem repeat typing analysis. MIRU-VTNR is a PCR-based genotyping assay. The CDC genotyping program currently performs 24-locus MIRU-VNTR analysis on every isolate submitted for genotyping. Before 2009, only 12-locus MIRU-VNTR was performed.

Mycobacterium bovis

A member of the *M. tuberculosis* complex that is commonly associated with cattle, particularly in the developing world. In the United States, human cases of *M. bovis* TB generally have a foodborne origin, such as through consumption of unpasteurized dairy products. *M. bovis* is typically resistant to pyrazinamide (PZA). Identification of TB isolates that are *M. bovis* can be done through genotyping; however, this information should not be relied on for clinical decision making.

***Mycobacterium tuberculosis* complex**

Often abbreviated MTC, a group of closely related mycobacterial species that can cause latent TB infection (LTBI) and TB disease (i.e., *M. tuberculosis*, *M. bovis*, *M. bovis BCG*, *M. africanum*, *M. canetti*, *M. microti*, *M. pinnipedii*, and *M. mungi*). In humans, most TB is caused by *M. tuberculosis*.

NTGS

The National TB Genotyping Service has provided TB genotyping services to local and state TB control programs since 2004. Two national genotyping laboratories are contracted by CDC to provide genotyping services at no cost to the patients, healthcare providers, or health departments.

NTSS

National TB Surveillance System administered by CDC. NTSS collects surveillance data through an electronic reporting registry. Data collected include socio-demographic, clinical, and risk factor variables that are reported to CDC by states and local health departments.

PCR

Polymerase chain reaction (PCR) is a laboratory method that can rapidly amplify small quantities of DNA, thereby enabling certain types of laboratory testing. The national genotyping laboratories routinely use two PCR-based techniques, spoligotyping and MIRU-VNTR analysis.

PCRTyp

A designation for each a unique combination of spoligotype and 12-locus MIRU–VNTR results. PCRTyp is designated as “PCR” followed by five digits, which are assigned sequentially to every genotype identified in the U.S. (e.g., PCR01974).

Recent Transmission

Although the precise time interval is not well defined, “recent” transmission for TB is often considered to be TB disease that is due to exposure 2-3 years prior to disease onset. That is, the chain of transmission spanning from exposure to source case through onset of symptoms for secondary cases would be <3 years. Immunocompromised patients (e.g., patients with HIV or diabetes) may be at a higher risk for acquiring TB disease.

Relapse vs. reinfection

A case of relapsed TB represents a worsening of signs and symptoms of disease after a period of improvement, caused by the same strain of *M. tuberculosis*. TB that represents a new infection (or reinfection) is disease caused by a second infection (often with a strain that is different from the strain that caused the initial infection). Genotyping the initial and the subsequent *M. tuberculosis* isolate might distinguish these two possibilities.

RFLP

Restriction fragment length polymorphism. Also called IS6110-based restriction fragment length polymorphism (RFLP) analysis was the first widely used method for genotyping *M. tuberculosis* isolates. A genotyping technique based on measuring the number and length of specific DNA fragments that are cut using specific restriction enzymes.

RVCT

Report of a Verified Case of TB. National surveillance data on patients with tuberculosis is recorded on this form, and subsequently reported to CDC’s National TB Surveillance System (NTSS).

Spoligotyping

Spacer oligonucleotide genotyping. A genotyping technique based on spacer sequences found in the direct repeat region in the chromosomes (genetic makeup) of the *M. tuberculosis* complex. The “spoligotype” is reported as a 15-digit number.
