**Candida auris** Information for Patients and Family Members

Español (Spanish).

*Candida auris* (C. auris) is a type of fungus that can cause serious illness in hospitalized patients. Infections with this fungus can be difficult to treat. C. auris only recently appeared in the United States, and public health officials are researching more about how it is spread. Here's what you need to know if you or a family member have a C. auris infection.

### What are the symptoms of C. auris infection?

- Symptoms may not be noticeable, because patients with C. auris infection are often already sick in the hospital with another serious illness or condition.
- Symptoms of C. auris infection depend on the part of the body affected. C. auris can cause many different types of infection, such as bloodstream infection, wound infection, and ear infection.
- Because symptoms can vary greatly, a laboratory test is needed to determine whether a patient has a C. auris infection.

### Who is most likely to get C. auris infection?

- C. auris mainly affects patients who already have many medical problems.
- It often affects people who have had frequent hospital stays or live in nursing homes.
- C. auris is more likely to affect patients who have weakened immune systems from conditions such as blood cancers or diabetes, receive lots of antibiotics, or have devices like tubes going into their body (for example, breathing tubes, feeding tubes, catheters in a vein, or bladder catheters).
- Healthy people usually don’t get C. auris infections.

### Are C. auris infections treatable?

- Most C. auris infections are treatable with a class of antifungal medications called echinocandins.
- Some C. auris infections have been resistant to all three main classes of antifungal medications, making them difficult to treat. In this situation, multiple antifungal medications at high doses may be needed to treat the infection.

### How serious can C. auris infection be?

- Any invasive infection, which includes bloodstream infection with any Candida species, can be serious and even fatal.
- Many people who have died with C. auris had other serious illnesses that increased their risk of death.

### Why does a patient with C. auris infection need special precautions during care?

- C. auris can spread from one patient to another in healthcare settings, such as hospitals and nursing homes, even if C. auris is on the skin or other body sites and the patient does not have symptoms.
- Special precautions reduce the chance of spreading the fungus to other patients. These precautions may include:
  - Placing the patient in a different room.
  - Having healthcare personnel or other caregivers wear gowns and gloves during patient care.
  - Cleaning the room with different products than usual.
  - Having family members and healthcare personnel clean their hands thoroughly after visiting the patient. The patient may also be encouraged to wash their hands often.

### How long does a patient with C. auris need to be under these special precautions?

400 West King Street, Suite 300 ● Carson City, Nevada 89703
775-684-4000 ● Fax 775-684-4010 ● dhhs.nv.gov

Page 1 of 2
• Even after C. auris infection is treated, patients might continue to have C. auris on their skin or other body sites that doesn’t cause infection or illness but can still spread to other patients.
• Special precautions should continue as long the patient has C. auris on the skin or other body sites. In most situations, precautions should be continued for the entire duration of the patient’s stay in a healthcare facility. More about the duration of precautions can be found in CDC’s infection control guidance.

Can a nursing home patient with C. auris participate in activities with others, such as meals or social gatherings, if they are on these special precautions?

• In general, residents of nursing homes who have C. auris on their skin or other body sites or are sick with a C. auris infection can leave their rooms to attend meals and group functions if:
  o They can wash their hands thoroughly on a regular basis.
  o Wounds are bandaged to prevent any fluids from seeping out and infecting others.
  o Other types of secretions like phlegm are contained.
  o Items that residents touch often and shared equipment (for example, physical therapy equipment or recreational resources) should be cleaned and disinfected after use.

Can family members get sick?

• Family members who are healthy probably have a low chance of C. auris infection.
• C. auris is mainly a problem among people who are already sick with multiple medical problems and have spent a lot of time in healthcare settings.
• Family members and others caring for patients with C. auris should wash their hands thoroughly before and after touching the patient or touching medical devices.
• Handwashing is particularly important if the caregiver is caring for more than one ill person at home.
• Ask and remind healthcare personnel to wash their hands.

Should family members or other close contacts of patients be tested for C. auris?

• In most instances, CDC does not recommend that family members or other close contacts of patients with C. auris infections be tested for C. auris.
• However, if someone who has frequent contact with a patient with C. auris is admitted to a healthcare facility, a healthcare provider might test them for C. auris to determine if special precautions should be used.

What should people who have tested positive for C. auris do after being discharged from healthcare facilities?

• People who have tested positive for C. auris should inform healthcare providers that they have tested positive for C. auris when visiting healthcare offices and when being admitted to hospitals and nursing homes.
